Symmetry and Aesthetics in Contemporary Physics
CS-10, Spring 2016
Dr. Jatila van der Veen

CLASS 9:
Symmetry: The Search Continues
Looking for deeper symmetries and spontaneous symmetry breaking

\[ S = \int dx \sqrt{g} \left[ \frac{1}{G} R + \frac{1}{g^2} F^2 + \psi \mathcal{D} \psi + (D \phi)^2 + V(\phi) + \overline{\psi} \phi \psi \right] \]

p. 111: To say that physics possesses a certain symmetry, is to say that the \textit{Action} is invariant under the transformation associated with that Symmetry.

\textbf{Action}: path of stable energy, \textit{invariant to rotations}, path of maximum proper time
Figure 9. Classification of symmetry
A gauge theory is a type of field theory in which the Lagrangian is invariant under a continuous group of local transformations – i.e., depend on spacetime.

- When the symmetry group depends on spacetime, it is called a *local symmetry*.
- The continuous symmetry that depends on spacetime is called a *gauge group*.
- The transformation that depends on spacetime is called a *gauge transformation*.

Yang-Mills Theory: a gauge theory in which a *field* is defined everywhere in space, mediated by the exchange of *virtual particles*

\[ \Delta E \Delta t \leq \hbar \]
...but first, a short excursion into SO(n) and SU(n):

Special Orthogonal Groups of order n: SO(n) are defined:

$O^T O = 1$ and $\det O = 1$ and has $n(n-1)/2$ degrees of freedom

The group SO(n) consists of rotations in n-dimensional Euclidean space, represented by n-dimensional tensors. SO(n) represents GLOBAL symmetries that are independent of spacetime.

**SO(2):**
for a counter-clockwise rotation:

$$R(\theta) = \begin{pmatrix} \sin \theta & \cos \theta \\ -\cos \theta & \sin \theta \end{pmatrix}$$

**SO(3):**
for 3 dimensions, just add the z-axis:

$$R(\varphi) = \begin{pmatrix} \sin \varphi & \cos \varphi & 0 \\ -\cos \varphi & \sin \varphi & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
Rotations in spacetime are SO(4)

\[ \gamma = \frac{1}{\sqrt{1 - \frac{v^2}{c^2}}} \]

\[ \beta = \frac{v}{c} \]

or, \( v = \beta c \)

Define:

\[ x' = \gamma (x - vt) \]

\[ t' = \gamma \left( t - \frac{\beta x}{c} \right) \]

Lorentz Transformation: the rule that translates between inertial reference frames in spacetime

For motion along the x-axis:

\[
\begin{bmatrix}
  x' \\
  y' \\
  z' \\
  t'
\end{bmatrix} = \begin{bmatrix}
  \gamma & 0 & 0 & -\gamma \beta c \\
  0 & 1 & 0 & 0 \\
  0 & 0 & 1 & 0 \\
  -\frac{\gamma \beta}{c} & 0 & 0 & \gamma
\end{bmatrix}
\begin{bmatrix}
  x \\
  y \\
  z \\
  t
\end{bmatrix}
\]

Global symmetry in Minkowski spacetime (no mass, no gravity)
SU(n): Special Unitary groups of order n

*complex* unitary matrices (det $U = 1$)

SU(n) represent **local** symmetries that DO depend on local variations in spacetime.

Examples: GR and symmetries in particle physics which depend on local FIELDS, i.e. *gauge theories*
Examples of Gauge Theories

Quantum Electro-Dynamics

QED has the gauge group = U(1) E&M. The number of gauge fields is \( \dim(U(1)EM) = 1 \). This gauge field is the photon. It couples to charged leptons and quarks.

Does SSB occur: No. So the photon remains massless.
U(1) is the group of all possible phase multiplications $e^{i\alpha}$.

\[
\Psi(x) \rightarrow e^{i\alpha} \Psi(x) \ ; \ \overline{\Psi}(x) \rightarrow e^{-i\alpha} \overline{\Psi}(x)
\]

\[
e^{i\alpha} = \cos \alpha + i \sin \alpha
\]
Examples of Gauge Theories: Quantum Chromo-Dynamics

QCD has the gauge group $SU(3)_{\text{color}}$. A gauge transformation is $U \in SU(3)_{\text{color}}$. QCD offers a new way of thinking about matter.

Every quark field of flavor $f$, say $f(x)$, has an associated color of red, green or blue. Define

$$\chi^f(x) = \begin{pmatrix}
\Psi^f_{\text{red}}(x) \\
\Psi^f_{\text{green}}(x) \\
\Psi^f_{\text{blue}}(x)
\end{pmatrix}$$

Construct the gauge-invariant Lagrangian:

$$\mathcal{L} = \bar{\chi}^f (i\gamma^\mu D_\mu - m) \chi^f$$

This Lagrangian must be invariant to ‘rotations’ in $SU(3)$. There are $3^2 - 1 = 8$ degrees of freedom, which are the 8 gluon fields.
The color symmetry of quarks is an exact symmetry: each quark can be transformed into a different ‘color’ quark.

\[
\begin{align*}
 r &= \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \\
 g &= \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} \\
 b &= \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}
\end{align*}
\]

Only around 2% of the mass of the proton comes from the three valence quarks. The rest comes from the gluon field and virtual quarks.
“Eightfold Way” representation of the spin $\frac{1}{2}$ baryons

- Isospin
- Charge
- Strangeness

Diagram shows the relationships between different baryon types based on their isospin, charge, and strangeness.
Almost symmetries of the spin 3/2 baryons
The Electro-Weak theory has the gauge group SU(2)$_{\text{left}} \times U(1)_{\text{hypercharge}}$. The number of gauge fields is equal to $\dim(SU(2)_{\text{left}} \times U(1)_{\text{hypercharge}}) = 4$. The gauge fields are the $W^a_\mu$, $B_\mu$, $a = 1, 2, 3$. Does SSB occur? Yes.

After SSB, the massive gauge fields are called $W^\pm_\mu$, $Z^0_\mu$ while the massless gauge field is called the photon.

The $W^\pm_\mu$ couple to left handed matter causing flavor changing processes like beta decay, the $Z^0_\mu$ couples to all particles and the photon couples to charged matter.
and flavor oscillations among neutrinos

FLAVOR OSCILLATIONS

When created or detected, a neutrino has a specific flavor. For instance, the beta decay of a neutron creates an electron-neutrino. This neutrino has no specific mass but is a mix of all three possibilities—represented by a sum of three waves with different wavelengths. As the neutrino propagates, the waves become misaligned, so they no longer add up to the original flavor but to some mix of all three flavors. The mix varies as the neutrino travels. Here the average mix is 5:2:2—which means a detector has a five-ninths chance of seeing it as an electron-neutrino and a fourth-ninths chance as a muon- or a tau-neutrino.

Electroweak Theory

Grand Unified Theory

Theory of Everything
The four different forces are now seen as broken symmetries in a low-energy universe, reduced from a higher symmetry at higher energies in the first instants after “creation.”

GUT scale: $t \sim 10^{-43}$ sec, $E \sim 10^{19}$ GeV
Almost symmetries: A symmetric theory can have asymmetric consequences. For example, the equations of a ball and the wheel of a roulette are symmetric with respect to the rotation axis, but the ball always keeps lying in an asymmetric position.
The symmetric state is not the state of minimum energy, i.e., the ground state, and in the process of evolving towards the ground state, the intrinsic symmetry of the system has been broken.
The symmetric state is not the state of minimum energy, i.e., the ground state, and in the process of evolving towards the ground state, the intrinsic symmetry of the system has been broken.

A small perturbation will cause the rotational symmetry to be broken and the system to assume the ground state configuration.
Nothing is unstable!

- Professor Rocky Kolb
  Fermilab, 1995
  personal communication
The symmetric state is not the state of minimum energy, i.e., the ground state, and in the process of evolving towards the ground state, the intrinsic symmetry of the system has been broken.

A small perturbation will cause the rotational symmetry to be broken and the system to assume the ground state configuration.

When the symmetry of a physical system is broken in this way, it is often referred to as "spontaneous symmetry breaking" (SSB).
The symmetric state is not the state of minimum energy, i.e., the ground state, and in the process of evolving towards the ground state, the intrinsic symmetry of the system has been broken.

A small perturbation will cause the rotational symmetry to be broken and the system to assume the ground state configuration.

When the symmetry of a physical system is broken in this way, it is often referred to as "spontaneous symmetry breaking" (SSB).

And this is how our current cosmological model explains how the universe came into existence!
