The software described in this documentation (CLOUDY) is subject to a FreeBSD-style software license contained in the file license.txt in the root directory of the distributed files. The list of co-authors is given in the file others.txt in the same directory. Use of this program is not restricted provided each use is acknowledged upon publication. The bibliographic reference to this version of CLOUDY is “version xx.xx of the code last described Ferland et al. (2013).” The version number, shown here as “xx.xx”, should be given. This version number, along with a complete citation, can be found by executing the code with the print citation command included in the input script.

CLOUDY is an evolving code. You should confirm that you have the most recent version of the code by checking the web site www.nublado.org. The code has a discussion board with emailing list. This will have announcements of any updates to the code.

Portions of the documentation have been published, and are copyrighted by, the American Astronomical Society, the Astronomical Society of the Pacific, and the Royal Astronomical Society. The remainder of the documentation is subject to the following FreeBSD format documentation license:

Redistribution and use of the documentation (all parts of HAZY and the Quick Start Guide) in source (LATEX) and ‘compiled’ forms (PDF, PostScript, HTML and so forth) with or without modification, are permitted provided that the following conditions are met:

1. Redistributions of source code (LATEX) must retain the above copyright notice, this list of conditions and the following disclaimer as the first lines of the file license_doc.txt in the root directory unmodified.

2. Redistributions in compiled form (converted to PDF, PostScript, XML, HTML and other formats) must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

This documentation is provided by the CLOUDY project “as is” and any express or implied warranties, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose are disclaimed. In no event shall the CLOUDY project be liable for any direct, indirect, incidental, special, exemplary, or consequential damages (including, but not limited to, procurement of substitute goods or services; loss of use, data, or profits; or business interruption) however caused and on any theory of liability, whether in contract, strict liability, or tort (including negligence or otherwise) arising in any way out of the use of this documentation, even if advised of the possibility of such damage.

Cover image: The spectrum emitted by a cloud with solar abundances, a temperature of \(10^7\) K, a density of \(10^{10}\) cm\(^{-3}\), and a column density of \(10^{15}\) cm\(^{-2}\). This shows recent improvements in the X-ray spectrum and was done with the test case coll_t7.in located in tsuite/auto. The command set continuum resolution 0.1 was added to increase the continuum resolution by a factor of ten.

OUTPUT

1.1 Overview

This section defines the output produced by CLOUDY. Each section begins with a sample of the output described, and then goes on to describe the meaning of the printout in greater detail. The output actually shown is from the Orion H II Region / PDR / molecular cloud test case (orion_hii_pdr_pp.in).

1.2 Header Information

Several lines of output echo the input commands and outline some properties of the initial continuum.

```
  Cloudy 06.01.02
  ******************************************************************************
  * title the Orion HII Region / PDR / Molecular cloud with an open geometry *
  * c commands controlling continuum ========= *
  * c the incident continuum is two parts *
  * c kurucz continuum and flux of photons striking cloud *
  * c this is the photosphere of the OVI star, its temperature and phi(H) *
  * table star kurucz 3960K *
  * phi(H) 13 *
  * c this adds the observed hot brems *
  * c its temperature (as log of T) and the flux of *
  * c photons striking the cloud *
  * brems 6 *
  * phi(h) 10 *
  * c *
  * c cosmic rays are important for pdr chemistry *
  * c cosmic rays, background *
  * c commands controlling geometry ========= *
  * c this turns off the stop temperature option *
  * c so the sim will not stop due to temperature *
  * stop temperature off *
  * c this sets the thickness of the HII region & PDR *
  * stop thickness 0.5 linear parsec *
  * c this will result in a milli gauss B-field in molecular region *
  * magnetic field -5 gauss *
  * c assume constant pressure *
  * constant pressure *
  * set nend 2000 *
  * c other commands for details ========= *
  * failures 3 *
  * c mimic existence of unmodeled molecular gas *
  * double *
  * c iterate since lines optically thick *
  * iterate *
  * c set microturbulence in equipartition with B field *
```
This begins with the version number of CLOUDY, the date that the version was released, in the form yy.mm.dd. The following line gives this date in another form.

All of the input command lines, with the exception of those starting with a #, %, or *, are echoed before the calculation begins, and are saved to be reprinted after the calculation is completed.

This block of information describes the continuum that strikes the illuminated face of the cloud. The full block of information is shown above, and in the following discussion each line is given again just before it is described.

This gives the number of numerical frequency cells in the continuum followed by the energy (in Ryd) of the peak of hydrogen-ionizing continuum. This is the point with the largest flux density per unit energy interval ($J_\nu$). Next is the energy of the low-energy limit of the continuum, in both Ryd and cm. The last two numbers are the energies of the high-energy limit of the continuum in Ryd and MeV.

This line gives the intensity or luminosity of the continuum source. Luminosities are printed if the inner radius of the cloud is specified. The units will be energy radiated by the central object into $4\pi$ sr [erg s$^{-1}$]. If an inner radius is not set then the code will compute the intensity case and give the emission per unit area of cloud surface. This is loosely called the intensity but is more formally $4\pi J$ where $J$ is the proper mean intensity [erg cm$^{-2}$ s$^{-1}$ sr$^{-1}$ for an emission line; AGN3 Appendix 1].

The line gives the log of the energy (erg s$^{-1}$ cm$^{-2}$ or erg s$^{-1}$, depending on whether it is the intensity or luminosity case) in the hydrogen-ionizing continuum (1 Ryd $\leq h\nu < 100$ MeV), and
the average energy of the hydrogen-ionizing continuum, in Ryd, weighted by photon number;
\[ \langle h\nu \rangle = \frac{\int_{1\text{Ryd}}^{\infty} 4\pi J_\nu \, d\nu}{\int_{1\text{Ryd}}^{\infty} 4\pi J_\nu / h\nu \, d\nu} \text{[Ryd].} \] (1.1)

The log of the energy in the X-ray continuum (20.6 Ryd \( \leq h\nu \leq 7676 \text{ Ryd} \)) is followed by the log of the energy (erg s\(^{-1}\) cm\(^{-2}\) or erg s\(^{-1}\)) and the number of photons (cm\(^{-2}\) s\(^{-1}\) or s\(^{-1}\)) in the Balmer continuum (0.25 Ryd to 1.0 Ryd).

\( \phi(1.0-1.8):12.9508 \quad \phi(1.8-4.0): 12.033 \quad \phi(4.0-20): 9.388 \quad \phi(20--): 7.634 \quad \text{Ion pht flx:1.001E+13} \)

The third line gives the log of the number of photons (cm\(^{-2}\) s\(^{-1}\) or s\(^{-1}\)) in four frequency bins (1.0 Ryd \( \leq h\nu < 1.807 \text{ Ryd}, 1.807 \text{ Ryd} \leq h\nu < 4.0 \text{ Ryd}, 4.0 \text{ Ryd} \leq h\nu < 20.6 \text{ Ryd}, \text{ and } 20.6 \text{ Ryd} \leq h\nu < 7676 \text{ Ryd} \)). The last number “Ion pht flx” is the flux of hydrogen ionizing photons;
\[ \Phi(H^0) = \frac{Q(H^0)}{4\pi r^2} \text{ [cm}^{-2}\text{s}^{-1}]. \] (1.2)

In this equation \( Q(H^0) \) is the total number of hydrogen-ionizing photons emitted by the central object (s\(^{-1}\)), and \( r \) is the separation between the center of the central object and the illuminated face of the cloud. Unlike the majority of the quantities printed in the header, \( \Phi(H^0) \) (per unit area) is always printed, never \( Q(H^0) \) (into 4\(\pi\) sr).

\( \text{I(gam ray): 0.0000 \quad \phi(gam r): 0.0000 \quad I(Infred): 1.5064 \quad Alf(ox): 0.0000 \quad Total inten: 3.0012} \)

The fourth line of the header gives some information about the low and high energy portions of the incident continuum. The first number is the log of the luminosity or intensity in the gamma-ray (\( \sim 100 \text{ keV to } \sim 100 \text{ MeV} \)) continuum. The second number is the log of the number of photons over this energy range. The third number is the log of the luminosity in the continuum between 0.25 Ryd and the lowest energy considered, presently an energy of 1.001 \( \times \) 10\(^{-8} \) Ryd. All of these entries are either per unit area, or radiated into 4\(\pi\) sr, depending on whether the intensity or luminosity case was specified.

The entry “Alf(ox)” is the spectral index \( \alpha_{\text{ox}} \), defined as in Zamorani et al. (1981), except for the difference in sign convention. This is the spectral index which would describe the continuum between 2 keV (147 Ryd) and 2500 Å (0.3645 Ryd) if the continuum could be described as a single power-law, that is,
\[ \frac{f_\nu(2 \text{ keV})}{f_\nu(2500 \text{ Å})} = \left( \frac{\nu_{2 \text{ keV}}}{\nu_{2500 \text{ Å}}} \right)^{\alpha} = 403.3^{\alpha}. \] (1.3)

The definition of \( \alpha_{\text{ox}} \) used here is slightly different from that of Zamorani et al. since implicit negative signs are never used by CLOUDY. Typical AGN have \( \alpha_{\text{ox}} \sim -1.4 \). If no X-rays are present then \( \alpha_{\text{ox}} = 0 \). The last number on the line is the log of the total energy in the continuum between 1.001 \( \times \) 10\(^{-8} \) Ryd and 100 MeV.

\( \log L/L_{\odot}: 3.9743 \quad \text{Abs bol mgs: } -5.1858 \quad \text{Abs V mag: 2.4170} \quad \text{Bol cor: } -7.6028 \quad \text{nuFnu(Hbeta): 34.5867} \)

This line is optional, depending on whether the luminosity or intensity case is specified. (It was not printed in this model since we are working in the intensity case but a sample is shown). This is printed in the luminosity case. First comes the log of the total luminosity in the continuum in solar units. The absolute bolometric magnitude, absolute V magnitude, and the bolometric correction, are then given, followed by the log of the continuum specific luminosity \( [\nu F_\nu(H\beta)] \) at the wavelength of H\(\beta\) [erg s\(^{-1}\)].
This line begins with two ionization parameters. The first is the dimensionless ratio of ionizing photon to hydrogen densities, defined as

$$U \equiv \frac{\Phi(H^0)}{n_H c},$$

where $n_H$ is the total hydrogen density. The second number is defined in a similar way, but the numerator is the number of photons with energies greater than 4 Ryd (i.e., helium-ionizing). The third number is the equivalent black-body temperature corresponding to the energy density at the illuminated face of the cloud, from the incident continuum and Stefan’s radiation density constant $a$;

$$T_u \equiv \left(\frac{L}{4\pi r^2 ac}\right)^{1/4} [K].$$

$T(\text{Comp})$ is the Compton temperature of the incident radiation field. The last number is $4\pi\nu J(912\AA)$, the flux at 912\AA\ (erg cm$^{-2}$ s$^{-1}$), where $J(\nu)$ is the mean intensity of the incident continuum (Mihalas, 1978).

These lines give dimensionless photon occupation numbers $\eta(\nu)$, for the incident continuum at several energies. The occupation number is defined as

$$\eta(\nu) \equiv J(\nu) \left(\frac{2h\nu^3}{c^2}\right)^{-1},$$

and the incident continuum brightness temperature $T_b(\nu)$, [K] is defined as

$$T_b(\nu) \equiv J(\nu) \left(\frac{2k\nu^2}{c^2}\right)^{-1} [K].$$

These energies correspond to the lowest frequency considered (presently $1.001 \times 10^{-8}$ Ryd); the ionization potential of the $n = 6$ level of hydrogen ($1/36$ Ryd); one Rydberg; four Rydbergs, and the high-energy limit of the incident continuum. The energy where the last number is evaluated depends on the continuum shape. The energy is given by the fifth number on the first line of the continuum output.

### 1.3 Chemical composition

**Gas Phase Chemical Composition**

**Grain Chemical Composition**

- C : -3.6259  O : -3.9526  Mg: -4.5547  Si: -4.5547  Fe: -4.5547

Number of grains per hydrogen

- Carbonaceous: -14.166  silicate: -14.103

---

1For a blackbody radiation field $T_{\text{Compton}}$ is roughly 4% lower than the blackbody color temperature $T_{\text{color}}$ when the energy density temperature $T_u$ is $> T_{\text{color}}$. Only when $T_u \equiv T_{\text{color}}$ does induced Compton heating cause $T_{\text{Compton}} \equiv T_{\text{color}}$. If $T_u > T_{\text{color}}$ then $T_{\text{Compton}} > T_{\text{color}}$ because of induced Compton heating. All of the relevant physics is included in the Compton temperature printed here.
The chemical composition of the cloud comes next. The three blocks of numbers give the gas-phase abundances of the elements, the abundances contained in grains, and the number of each type of grains per unit hydrogen. The numbers are the logs of the number densities of the elements, relative to the gas-phase hydrogen abundance of unity (so, 0 on the log scale). Only the active elements are included (those turned off with the elements off command are not printed). If grains are not present then the second two blocks are not printed.

### 1.4 Comments before or during the calculation

The code may print comments as the calculation proceeds. These are printed with the start of the comment in capital letters to make them easy to find with a script. The comments fall into three categories:

- **DISASTER** something has unexpectedly caused the calculation to stop. The results are bogus and should not be trusted. The code should immediately return to the calling program.

- **PROBLEM** something did not go as expected but the calculation is continuing. This might be a convergence failure at a point in the cloud. This is an indication that the code was having difficulties and a few of these can occur in a normal set of calculations. The predictions can be used if only a few occur and if the comments at the end of the calculation (see page 9 below) do not identify other problems.

- **NOTE** this gives advice about the calculation. These can be ignored if you prefer.

### 1.5 Zone Results

Next comes a summary of the conditions in the first and last zone. This print out is done in routine PrtZone which should be consulted if there are any questions. The following is the output produced for one zone. Details follow.
The results of calculations for the first and last zones are always printed. Results for intermediate zones can be printed if desired (see the print every command). The following is a line-by-line description of the output produced for each printed zone.

</table>

A line describing the velocity and acceleration of the zone is printed if the cloud is a wind. The numbers are the wind velocity at the outer edge of the current zone (km s⁻¹), inward gravitational acceleration (cm s⁻²), total outward radiative acceleration (cm s⁻²), and the fraction of this acceleration caused by the incident continuum, line driving, and the gradient of the radiation pressure.

A line describing the source of the radiation pressure is generated if the ratio of line radiation to gas pressure, $P_{\text{rad}}/P_{\text{gas}}$, is greater than 5%. The line begins with the label “P(Lines)” and continues with the fraction of the total radiation pressure produced by that emission line, the spectroscopic designation of the line, and its wavelength. Up to twenty lines can be printed, although in most cases only Ly$\alpha$ and a few others will dominate.

---

The `CLOUDY` software defines heating as the energy input by the freed photoelectron, or $h\nu-IP$, where IP is the ionization potential of the atom or ion, and $h\nu$ is the energy of the photon. See AGN3 for more details.
The line begins with the ratios \( n(H^0)/n(H_{tot}) \) and \( n(H^+)/n(H_{tot}) \) where \( H_{tot} \) is the total density in \( H \) all forms (including molecular). If **print h-like departure coefficients** has been specified then departure coefficients are also printed on the following line. Neutral hydrogen \( H^0 \) is defined to be the total population of atomic hydrogen in all explicitly computed bound levels. Next comes “H+o/Hden”, the ratio \( [n(H^0) + n(H^+)}/n(H_{tot}). \)

The following five numbers give densities of the negative hydrogen ion and several molecules (\( H^- \), \( H_2 \), \( H_3^+ \), and \( HeH^+ \)) relative to the total hydrogen density. Note that, with this definition of the hydrogen density, a fully molecular gas will have \( n(H_2)/n(H) = 0.5 \). These molecular abundances are also expressed as departure coefficients if the **print departure coefficients** command occurs. The last number is the \( H^0 \) and \( H^+ \) column densities (cm\(^{-2}\)).

This information is only printed if the **print H-like populations** command occurs. The numbers give the populations of the \( H^0 \) levels relative to the ionized hydrogen density. All of these populations usually are relative to the ionized hydrogen density, but can also be printed as LTE departure coefficients if the **print departure coefficients** command is given.

The first three numbers are the total populations of the three ionization stages of helium relative to the total helium abundance. The population of atomic helium is the sum of the total population in the triplets and singlets, including the population of all explicitly computed levels of each. These populations can also be expressed as departure coefficients if this option is set with the **print departure coefficients** command. The population of He \( 2^3S \), relative to the total helium abundance, follows. The Compton heating and cooling rates (both erg cm\(^{-3}\) s\(^{-1}\)) are next, followed by the gas filling factor. The last number is the fraction of the total hydrogen ionizations that are caused by photoionization from the ground state.

The first numbers are the level populations of the \( l \)-levels within \( n = 1 \) to 3 of the \( He^0 \) singlets. The next group consists of \( He^0 \) triplet populations of \( 2S \), the three \( 2^3P_j \) levels, and the \( 3S, 3P, \) and \( 3D \) levels. All populations are relative to the total helium abundance. Departure coefficients are also printed if requested.

Some information concerning the pressure is printed. The gas equation of state includes thermal gas pressure, the radiation pressure due to trapped line emission, magnetic and turbulent pressure, and the radiation pressure due to absorption of the incident continuum. The first number is the gas pressure \( n_{gas}T_{gas} \) (with units cm\(^{-3}\) K), followed by the total pressure (dynes cm\(^{-2}\)), and is followed by the gas pressure \( (n_{gas}kT_{gas}) \) in dynes cm\(^{-2}\). The radiation pressure follows. The second to last number is the radiative acceleration (cm s\(^{-2}\)) at the inner edge of this zone. The radiative acceleration is computed with all continuous scattering and absorption opacities included. The last number is a force multiplier, defined as in Tarter and McKee (1973), and is the ratio of total opacity to electron scattering opacity.
The second line gives more information. The line starts with “Texc(La)”, the excitation temperature $T_{\text{exc}}$ of La, defined as

$$\frac{n(2p)/g(2p)}{n(1s)/g(1s)} = \exp\left[-\frac{\hbar\nu}{kT_{\text{exc}}(La)}\right].$$

(1.8)

This is followed by the temperature corresponding to the energy density of the attenuated incident continuum (“T(contn)”) and the diffuse continua (“T(diffs)”). This includes all trapped lines and diffuse continuous emission. The entry “nT (c+d)” is the energy density of the sum of these two continua expressed as an equivalent pressure $nT$ [cm$^{-3}$ K]. The line ends with the ratios of the radiation to gas pressure “Prad/Gas” and the ratio of magnetic to gas pressure “Pmag/Gas”.

</tbody>
</table>

Some properties of the grain populations are printed if they are present. Each line gives the results of calculations for a specific type and size of grain. Graphite and silicate are normally included when grains are present. Each line begins with the name of the grain and an asterisk appears if quantum heating was important for the species. Quantum heating is only computed if it is significant due to its computational expense. The remainder of the line gives the equilibrium temperature of the grain, the potential in volts, the charge, the drift velocity, the gas heating (erg cm$^{-3}$ s$^{-1}$) due to grain electron photoemission, and the dimensionless fraction of the total gas heating due to grain electron photoemission. For quantum-heated grains the temperature is the average weighted by $T^4$.

Molecules

<table>

Abundances of each stage of ionization of lithium and beryllium relative to the total gas-phase abundance of the element are followed by the suprathermal secondary ionization rate $[s^{-1}]$.

A line giving relative abundances of some molecules is printed if the molecular fraction is significant. All molecular abundances are relative to either the total carbon or total oxygen abundance (this is indicated in the label for each). In order, the molecules are CH, CH$^+$, CO, CO$^+$, H$_2$O, and OH.
The abundances of the seven stages of ionization of carbon relative to the total gas-phase carbon abundance begin the line. The abundance of $\text{H}_2\text{O}^+$ and $\text{OH}^+$ relative to the total gas-phase oxygen abundance are given. These are followed by “Hex(tot)”, the extra heat (erg cm$^{-3}$ s$^{-1}$) due to fast neutrons, dissipation of turbulence, or added with the hextra command.

</table>

The relative populations of the eight ionization stages of nitrogen are printed first. The abundance of $\text{O}_2$ and $\text{O}_2^+$, relative to the total oxygen abundance, follows.

There are too many ionization stages to print across the line for elements more massive than neon. Although all stages with non-trivial abundances are computed, only the highest twelve stages of ionization are printed. The first number is an integer indicating how many stages are “off the page to the left”. If the number is 2, then the first printed stage of ionization is twice ionized, i.e., $\text{Fe}^{+2}$.

### 1.6 Comments after the calculation

The calculation stopped because outer radius reached. Iteration 1 of 2

A series of messages appear after the printout of the last zone. The first will say why the calculation stopped. In a valid calculation the model will stop because one of the specified stopping criteria specified was met. If no other criteria are specified then the calculation usually stops when the default lowest temperature of 4000 K is reached. If the code stops because of an unintended reason (i.e., internal errors, or reaching the default limit to the number of zones) then a warning is printed saying that the calculation may have halted prematurely.

Only one stopping criterion message will be printed. The possible messages, and their interpretations, are:

...because of radiation pressure By default a cloud will have constant density. CLOUDY will keep the total pressure, particle and radiation, constant if constant pressure is specified with the constant pressure command. The radiation pressure is small at the boundaries of the cloud, so the cloud will be unstable if the ratio of radiation to total pressure exceeds 0.5. The calculation stops, and this message is generated, if $P_{\text{rad}}/P_{\text{tot}} > 0.5$ occurs after the first iteration.

...because lowest EDEN reached The calculation can be forced to stop when the electron density ($\text{eden}$) falls below the value set by the stop eden command. This can be used to stop the calculation at an ionization front. The default lowest electron density is negative, so this stopping criterion occurs only when the command is entered.

...because low electron fraction The calculation can be forced to stop when the ratio of electron to hydrogen densities falls below a certain value, as set by the stop efrac command. This can be used to stop the calculation at an ionization front when the hydrogen density there is not known (for instance, in a constant pressure model). The default lowest electron density is negative, so this stopping criterion applies only when the command is entered.
...because large H$_2$/H fraction  The calculation can be forced to stop when the ratio of densities of molecular hydrogen to total hydrogen rises above the value set by the stop mfrac command. The molecular fraction is defined as $2n(H_2)/n(H_{tot})$. This can be used to stop the calculation at some depth into a PDR. The default highest molecular density is $>>1$, so this stopping criterion occurs only when the stop mfrac command is entered.

...because wind veloc too small  The code can perform a wind calculation which includes the outward force due to radiation pressure and the inward force of gravity. This message is printed if the gas decelerates to a stop.

...because code returned BUSTED  The calculation stopped because something bad happened. Please post the input script and version number on the discussion board.

...because DRAD small - set DRMIN  The Strömgren radius of the H$^+$ zone is estimated at the start of the calculation and the smallest allowed zone thickness is set to a very small fraction of this. The calculation will stop if the zone thickness falls below this smallest thickness. This can occur because of any of several logical errors within CLOUDY (adaptive logic is used to continuously adjust the zone thickness), although it can rarely occur for physical reasons as well. The smallest thickness can be reset to any number with the set drmin command but it should not be necessary to do this. Please post the input script and version number on the discussion board.

...because DR small rel to thick  The depth into the cloud is stored as the double precision variable depth and the zone thickness is stored as the double precision variable drad. If the zone size becomes too small relative to the depth ($drad/depth < 10^{-14}$) then the depth variable will underflow such that $depth + drad = depth$. The calculation will stop if this problem prevents the density from being properly evaluated.

...because optical depth reached  The largest allowed continuous absorption optical depth can be set with the stop optical depth command. The command specifies both the absorption optical depth, and the energy at which it is to be evaluated. Scattering opacities are not included since their effects are very geometry dependent. If the calculation stops because the largest continuum optical depth is reached, then this line is printed. This line is also printed if the stop effective column density command is used to stop the calculation, since this command is actually a form of the stop optical depth command.

...because outer radius reached  The default outer radius is unphysically large, but can be changed with the radius or stop thickness commands. If the calculation stops because the outer radius set by one of these commands is reached, then this line is printed.

because column dens reached  a limit to the largest allowed neutral, ionized, and total hydrogen column densities is set with the stop column density, stop neutral column density, or stop ionized column density commands. This message will be printed if one of these criteria stops the calculation.

...because lowest Te reached  The default value of the lowest temperature allowed is 4000 K. This is reasonable when only emission from warm ionized gas is of interest. The limit can
be changed with the `stop temperature` command. This message is printed if the calculation stops because the lowest temperature is reached.

...because highest Te reached  The default value of the highest temperature allowed is $1.001 \times 10^{10}$ K. The limit can be changed with the `stop temperature exceeds` command. This message is printed if the calculation stops because the highest allowed temperature is exceeded.

...because freeze out fraction  Nick Abel incorporated the condensation of molecules onto grain surfaces. Currently CO, H$_2$O, and OH condensation are treated. The chemistry network will become unstable when oxygen is highly depleted from the gas phase. By default the code stops when 99% of the oxygen abundance has condensed out of the gas phase.

...because NZONE reached  By default the code will stop after computing 1400 zones. This can be reset with the `stop zone` command. This message is printed if the calculation stops because the limiting number of zones is reached. A warning is printed at the end of the calculation since this was probably not intended.

   The default limit to the number of zones can be increased, while retaining the check that the default limit is not hit, by using the `set nend` command.

...because volume too large for this cpu  This indicates that the effective volume of the last zone was too large to be represented as a single precision floating point number. This happens when $R/R_{in}$ becomes really large. Usually this indicates that none of the intended stopping criteria were hit, so you should check those. If you really intend for the simulation to integrate this far, you should increase the inner radius.

...because line ratio reached  It is possible to set a limit to the largest value of an emission-line intensity ratio with the `stop line` command. This message is printed if the calculation stops because the largest value of the ratio is reached.

...because internal error - DRAD  An internal logical error caused this message to be printed. Please report the problem, including the command lines and the version number of CLOUDY, on the discussion board at the code’s web site.

...because initial conditions out of bounds  The temperature of the first zone was not within the temperature bounds of the code. This is probably due to the incident continuum not being set properly.

...because zero electron density  The electron density fell to zero because there was no source of ionization. This is unphysical and usually occurs because the cloud boundary conditions were not set properly. Consider adding at least galactic background cosmic rays with the `cosmic ray background` command and perhaps the galactic or extragalactic background.

...because reason not specified  This is an internal error. Please post the input and version number on the code’s discussion board.
1.7 Geometry

The geometry is plane-parallel.

The code will next say whether the geometry is plane parallel \((\Delta r/r_0 < 0.1)\), a thick shell \((\Delta r/r_0 < 3)\), or spherical \((\Delta r/r_0 \geq 3)\), where \(r_0\) is the inner radius and \(\Delta r\) is the thickness of the cloud.

1.8 Warnings, Cautions, Surprises, and Notes

- Cloud thicker than smallest Jeans length: \(3.51 \times 10^{16}\) cm; stability problems? (smallest Jeans mass: \(2.58 \times 10^{-1}\) Mo)
- Magnetic field & cosmic rays both present. Their interactions are not treated.
- Suprathermal collisional ionization of H reached 83.84\% of the local H ionization rate.
- \(N_2\) vib deexcitation reached 6.68\% of the local heating.
- Charge transfer ionization of H reached 95.8\% of the local H ionization rate.
- The largest continuum brightness temperature was 4.835 \times 10^{15} K at 1.052 \times 10^{-8} Ryd.
- Both constant pressure and turbulence make no physical sense?!
- AGN. Cloud age was not set. Longest timescale was 8.43 \times 10^{15} s = 2.67 \times 10^{8} years.
- The excitation temp of Ly\(\alpha\) exceeded the electron temp, largest value was 4.60 \times 10^{3} K (gas temp there was 1.01 \times 10^{3} K, zone 310).
- Warnings begin with “W-”; Cautions begin with “C-”; Surprises begin with an explanation mark (“!”); Notes.

The next messages fall into four categories: warnings beginning with “W-”; cautions beginning with “C-”; surprising results beginning with an explanation mark (“!”); and notes.

CLOUDY does many internal sanity checks to confirm that its range of validity was not exceeded (Ferland, 2001). Warnings are issued to indicate that the program has not treated an important process correctly. For instance, warnings occur if the temperature was high enough for the electrons to be relativistic, if the global heating - cooling balance is off by more than 20\%, or if the code stopped for an unintended reason. We would like to hear about warnings - the web site has a discussion board to place comments. Cautions are less severe, and indicate that CLOUDY is on thin ice. Examples are when the optical depths in excited states of hydrogen change during the...
last iteration. Surprises indicate that, while the physical process has been treated correctly, the result is surprising. An example is when induced Compton heating is more than 5 percent of the total Compton heating. Notes indicate interesting features about the model, such as maser effects in lines or continua, or if the fine structure lines are optically thick. The messages are usually self-explanatory.

### 1.9 Optional Plot

![Optional Plot Diagram]

If any of the optional plots are requested with a `plot` command then they will appear next. This option is seldom used today since it is much easier to create data files with save commands and then use other software to make plots.

### 1.10 Final Printout

```
********************************> Cloudy 06.01.02 <********************************
```
CHAPTER 1. OUTPUT

* title the Orion HII Region / PDR / Molecular cloud with an open geometry *
* c *
* c commands controlling continuum ========= *
* assert line luminosity "12CO" 235.4m -2.80 error 0.15 *
* assert line luminosity "12CO" 215.7m -2.84 error 0.15 *
* assert nzone < 1400 *
* assert itrzn < 24 *
* c orion hii pdr pp.in *
* c class hii pdr *
* c ======================================== *

The final printout begins by reprinting the input commands. The box surrounding it gives both
the version number of CLOUDY (at the top) and the log of the ionization parameter (the ratio of
ionizing photon to hydrogen densities) at the bottom.

Intensity (erg/s/cm²)

This line summarizes some properties of the model and output. The first part indicates whether
the energy in the emission lines is given as the luminosity case (the energy radiated by a spherical
shell covering $\Omega$ sr [erg s⁻¹] where $\Omega/4\pi$ is the covering factor) or the intensity case (emission
produced by a unit area of gas [erg s⁻¹ cm⁻²]). Which of the two choices is printed is determined
by whether the luminosity of the continuum was specified as the luminosity radiated by the central
object into $4\pi$ sr or the intensity ($4\pi J$) of the incident continuum (erg cm⁻² s⁻¹) at the
illuminated face of the cloud. If the cloud is spherical and the intensity case is computed then the
emergent emission-line spectrum will be per unit area in units of the inner radius $r_o$ (that is, the
total line luminosity radiated by a shell covering $4\pi$ sr will be the listed intensity $4\pi J \times 4\pi r_o^2$).
The second part of this line indicates the density structure (i.e., wind, constant density, constant
pressure, constant gas pressure, power-law density distribution, etc). The next section tells
whether the geometry was open or closed (these are defined in Part I of this document). The last
part indicates the iteration number.

A series of predicted quantities follow. These are mainly emission-line intensities although the
output also includes other predicted quantities.

Some continua and various indications of contributors to lines and continua are included. The
Chapter of this document describing observed quantities (starting on page 25) tells how to convert
these into some observed quantities. Not all are printed by default. The discussions on the print
commands in Part I tell how to get more or fewer predictions. This list of emission lines can also
be sorted by wavelength or intensity, and can be printed as a single column so that they can be entered into a spreadsheet.

The organization and meaning of the different of lines in the printout is discussed in the Chapter *The Emission Lines* starting on page 91.

A list of emission lines with negative relative intensities may follow the main block of lines. These are lines which heat rather than cool the gas (heating is negative cooling). This is not a problem but occurs if the line’s collisional de-excitation rate exceeds its collisional excitation rate. This usually occurs when the line is radiatively excited but collisionally de-excited.

### 1.10.1 Intrinsic line intensities and luminosities

There are two blocks of predicted intensities. The block “Intrinsic line intensities” is the intrinsic emission from the cloud. The intrinsic emission includes all processes that affect the line formation and transfer. This includes collisional processes, fluorescence, line destruction by background opacities such as dust or the Lyman continuum of hydrogen, and recombination. The intrinsic intensities do not include the effects of absorbers or scatters that do not lie within the line-formation region.

### 1.10.2 Emergent line intensities and luminosities

The block “Emergent line intensities” is the emission observed from outside the cloud. In an open geometry the inward part of the line includes the effects of extinction between the line-forming region and the illuminated face. There is an additional contribution due to reflection off the gas in the outward direction. The outward part of the line includes the effects of extinction between the shielded face and the point where the line forms. In a closed geometry the emergent intensity is the emission escaping to the outer edge of the slab. All of this is very geometry dependent. For an open geometry, in particular, the observed emission will depend strongly upon the viewing angle.

If the intrinsic and emergent values are very different then it is important to understand the geometry and what is actually observed. This is an indication of the uncertainty if the predictions have a strong geometry dependence.

### 1.10.3 Some physical properties of the cloud

*the Orion HII Region / PDR / Molecular cloud with an open geometry*

**Cooling**: This line indicates the fraction of the total cooling (defined here as the energy of the freed photoelectron, see AGN3 Chapter 3) carried by the indicated emission lines. The line label is followed by the ratio of the energy in the line to the total cooling. This is an important indication of the fundamental power-losses governing conditions in the model. The labels used are the same as those in the line array.

**Heating**: This line indicates the fraction of the total heating produced by various processes. The format is the same as the line giving the cooling.

**IONIZE PARMET**: $U(1-) = -1.4764$ $U(4-) = -5.0813$ $U(sp) = -4.46$ $Q(Ion) = -4.574$ $L(Ion) = 13.505$ $Q(low) = 15.158$ $L(low) = 1.121$
CHAPTER 1. OUTPUT

The line begins with the log of the H “U(1-)” and He⁺ “U(4-)” ionization parameters. The third number “U(sp)” is the log of a spherical ionization parameter often used in spherical geometries, such as H II regions or planetary nebulae. It is defined as

\[ U_{\text{ sph}} = \frac{Q(H^0)}{4\pi R_s^2 n_{\text{H}}} \]  \hspace{1cm} (1.9)

where \( R_s \) is the Strömgren radius, defined as the point where the hydrogen neutral fraction falls to \( H^0/H = 0.5 \). If no ionization front is present then \( U_{\text{ sph}} \) is evaluated at the outer edge of the cloud. The next two numbers are the log of the number of hydrogen-ionizing photons \( (h\nu \geq 1 \text{ Ryd}) \) exiting the nebula “Q(ion)” and the log of the energy in this continuum “L(ion).” The next two numbers are the equivalent quantities for non-ionizing \( (h\nu < 1 \text{ Ryd}) \) radiation. These are either per unit area or by a shell covering \( 4\pi \text{ sr} \). These have been corrected for the \( r^{-2} \) dilution if per unit area, and so are directly comparable with the numbers given at the start of the calculation.

ENERGY BUDGET: Heat: 1.725 Coolg: 1.725 Error: 0.0% Rec Lin: 1.462 F-F H -5.612 P(rad/tot)mx:1.10E-01

This line gives an indication of the energy budget of the nebula. The first number “Heat” is the log of the total heating (in ergs s\(^{-1}\), but again either into \( 4\pi \text{ sr} \) or cm\(^{-2}\)). The second number “Coolg” is the log of the total cooling, in the same units. Cooling is the total energy in collisionally excited lines and part of the recombination energy, but does not include recombination lines (AGN3 Chapter 3). The percentage error in the heating-cooling - cooling match “Error” follows. The next numbers give “Rec Lin”, the log of the total luminosity in recombination lines, “F-F H”, the log of the amount of energy deposited by free-free heating, and “P(rad/tot)mx”, the largest value of the ratio of radiation to gas pressures that occurred.

Col(Heff): 1.031E+25 and travl time 5.06E+13 sec Te-low: 1.69E+01 Te-hi: 1.08E+04 G0TH85:3.54E+05 G0DB96:4.54E+05

The effective column density “Col(Heff)”, as defined in the section in Part 1 on the stop effective column density command, is printed. This is followed by “snd travl time”, the sound travel time across the nebula in seconds. Constant pressure is only valid if the cloud is static for times considerably longer than this. The last two numbers are the lowest “Te-low” and highest “Te-hi” electron kinetic temperatures found in the computed structure. The last numbers “G0TH85” and “GHB96” give the intensity of the ultraviolet radiation field relative to the background Habing value, as defined by Tielens and Hollenbach (1985) and Bertoldi and Draine (1996).

Emiss Measure n(e)n(p) dl 2.205E+25 n(e)n(He+)dl 1.962E+24 En(e)n(He++) dl 1.402E+21

This gives several line-of-sight emission measures. The definition of the line of sight emission measure of a species X is (AGN3 section 5.4)

\[ E(X) = \int n(e) n(X) f(r) dr \quad [\text{cm}^{-5}] \]  \hspace{1cm} (1.10)

where \( f(r) \) is the filling factor. This is given for H⁺, He⁺, and He²⁺.
This line includes some quantities deduced from the predicted emission-line spectrum. The first ("He/Ha") number is the apparent helium abundance He/H, measured from the emission-line intensities using techniques described in AGN3 (Chapter 5);

$$\frac{\text{He}}{\text{H}}_{\text{apparent}} = \frac{0.739 \times I(5876) + 0.078 \times I(4686)}{I(H\beta)}. \tag{1.11}$$

The intensities of all lines are the total predicted intensities and include contributions from collisional excitation and radiative transfer effects. The second number (i.e., “1.07*true”) is the ratio of this deduced abundance to the true abundance. This provides a simple way to check whether ionization correction factors, or other effects, would upset the measurement of the helium abundance of the model nebula. This is followed by the longest wavelength in centimeters “Lthin” at which the nebula is optically thin. Generally the largest FIR opacity source is bremsstrahlung and the number will be $10^{30}$ if the nebula is optically thin across the full continuum. The number “itr/zn” is the average number of iterations needed to converge each zone while “H2 itr/zn” is the number of iterations per zone required to converge the large H2 model if it is included. “MassTot” gives the total mass of the computed structure in grams if the inner radius was specified. If the inner radius was not specified, and the cloud is plane parallel, then the mass per unit area [gm cm$^{-2}$] is reported.

</tr>
</tbody>
</table>

This line gives various quantities related to the H 1 21 cm line. “T(21cm/Ly a)” gives the temperature deduced from the ratio of the 21 cm to L$\alpha$ line optical depths (AGN3 Section 5.5). The opacity within the 21 cm line is proportional to $n(H^0)\chi/kT$ where $\chi$ is the excitation energy of the line. “T(<nH/Tspin>)” gives the harmonic mean temperature

$$\langle T \rangle = \frac{\int T n(H^0)\chi/kT \, dr}{\int n(H^0)\chi/kT \, dr} \tag{1.12}$$

where $T$ is the electron or gas kinetic temperature. “T(nH/Tspin)” is the temperature derived from the $n/T_{spin}$ ratio using the 21 cm spin temperature. $T_{spin}$ is calculated from the ratio of populations of the ground fine structure levels, which is computed including the effects of L$\alpha$ scattering. The spin and kinetic temperatures are often assumed to be equal although they are not in practice. The number “TB21cm“ is an estimate of the brightness temperature of the 21 cm line as viewed from the illuminated face of the cloud. It is the spin temperature at a depth where the 21 cm line becomes optically thick at line center.

On the next line the next two numbers are the H$^0$ and OH column densities divided by the 21 cm spin temperature in the case of H$^0$ and by the kinetic temperature in the case of OH. These ratios are proportional to the optical depth of a line at radio frequencies.

$a$:0.00E+00 erdeFe0.0E+00 Tcompt1.90E+06 Tthr1.19E+13 \langle T_{den} \rangle: 2.38E+01 \langle \text{dens} \rangle:2.00E-17  \langle \text{Mol} \rangle:2.31E+00

The mean radiative acceleration “$<a>$” [cm s$^{-2}$] is printed if the geometry is a wind model and zero otherwise. This is followed by some time scales. “erdeFe” is the time scale, in seconds, to photoerode Fe (Boyd and Ferland, 1987). This is 0s if the $\gamma$-ray flux is zero. The next gives the Compton equilibrium timescale “Tcompt” and the thermal cooling timescale “Tthr” [s]. The density (gm cm$^{-3}$) weighted mean temperature “$<T_{den}>$”, radius-weighted mean density “$<\text{dens}>$” (gm cm$^{-3}$), and mean molecular weight “$<\text{Mol}>$”, follow.
CHAPTER 1. OUTPUT

Mean Jeans l(cm): 4.19E+16 M(sun): 4.36E-01 smallest: l(len(cm)): 3.53E+16 M(sun): 2.61E-01 Alf(ox-tran): 0.0000

This gives the mean Jeans length “l(cm)” (cm) and Jeans mass “M(sun)” (in solar units). This is followed by the smallest Jeans length “smallest len(cm)” and the smallest Jeans mass “M(sun)” which occurred in the calculation. The last quantity “Alf(ox-tran)” is the spectral index $\alpha_{\text{ox}}$, defined as in the header, but for the transmitted continuum (attenuated incident continuum plus emitted continuum produced by the cloud).

Rion: 1.001E+17 Dist: 6.17E+21 Diam: 6.69E+00

This gives the radius of the hydrogen ionization front (in cm), or the outer radius in case the hydrogen ionization front is never reached. This is followed by the distance (in cm), or zero in case the distance command was not used. Finally the angular diameter of the ionized region is given (in arcsec), or zero if the distance was not set. The angular diameter is defined as $2 \times \text{Rion}/\text{Dist}$.

Hatom level 26 NHtopoff: 22 HatomType: add HInducImp Pe He tot level: 63 He2 level: 26 ExecTime 2233.72

This line gives the number of levels of the model hydrogen atom, the “topoff” level, above which the remainder of the recombination coefficient is added, the type of top off used for this calculation, and the number of levels used for the atomic helium. The last number on the line is the execution wall-clock time in seconds.

ConvrgError(%) <eden> 0.075 MaxEden 0.543 <H-C> 0.20 Max(H-C) 0.50 <Press> 0.142 MaxPress 2.535
Continuity(%) chng Te 3.9 elec den 5.8 n(H2) 12.8 n(CO) 8.5

The first line gives some estimates of the errors that occurred in several quantities that the code converges. A pair of numbers gives the mean and largest percentage errors for the electron density, the heating-cooling balance, and the pressure. The second line gives the percentage changes that occurred from one zone to the next for the temperature, the electron density, and the $\text{H}_2$ and CO densities.

1.10.4 Average temperatures and densities

This begins with several temperature and density averages, over either radius or volume. The volume averages are only printed if the sphere command is entered. The quantity which is printed is indicated at the top of each column. The quantity being averaged is the first part of the label, and the weighting used is indicated by the quantity in parenthesis. For instance “Te(\text{NeO}_2+))” is the electron temperature averaged with respect to the product of the electron and O$^{2+}$ densities.

Peimbert T(OIIIr) 9.08E+03 T(Bac) 0.00E+00 T(HH) 0.00E+00 t2(Hstrc) 6.01e-03 T(03-BAC) 0.00E+00 t2(03-BC) 0.00E+00 t2(03str) 1.81e-03 Be careful: grains exist. This spectrum was not corrected for reddening before analysis.

This series of quantities deal with temperature fluctuations ($t^2$, Peimbert, 1967; AGN3 section 5.11). The code analyzes the predicted emission line and continuum spectrum using the same steps that Manuel outlined in this paper. The code does not attempt to correct the predicted emission-line intensities for collisional suppression or reddening, so this line is only printed if the density is below the density set with the set tsqden command—the default is $10^7 \text{ cm}^{-3}$. This code does not attempt to deredden the spectrum: a caution is printed if grains are present.
The nature of temperature fluctuations is, in my opinion, the biggest open question in nebular astrophysics. Theory (CLOUDY too) predicts that they should be very small because of the steep dependence of the cooling function on the temperature, while some observations indicate a very large value of $t^2$ (see Liu et al., 1995, Kingdon and Ferland, 1995, and Ferland, 2003). If something is missing from our current understanding of the energy source of photoionized nebulae then the entire nebular abundance scale (for both the Milky Way and the extragalactic nebulae) is in error by as much as 0.5 dex.

Two fundamentally different $t^2$s enter here—the “structural” $t^2$ and the “observational” $t^2$. The structural value comes from the computed ionization and thermal structure of the nebula while the observational value comes from an analysis of the predicted emission-line spectrum following the methods outlined in Peimbert’s 1967 paper.

The structural $t^2$ for the H$^+$ ion is defined as

$$t^2 (\text{H}^+) = \left\langle \left( \frac{T(r) - \langle T \rangle}{T} \right)^2 \right\rangle = \frac{\int [T(r) - \langle T \rangle]^2 n_e n(\text{H}^+) f(r) \, dV}{\langle T \rangle^2 \int n_e n(\text{H}^+) f(r) \, dV} \quad (1.13)$$

where $\langle T \rangle$ is the density-volume weighted mean temperature

$$\langle T \rangle = \frac{\int T(r) n_e n(\text{H}^+) f(r) \, dV}{\int n_e n(\text{H}^+) f(r) \, dV} \quad (1.14)$$

This quantity is given in the averaged quantities block as the column “Te(NeNp).”

The observational $t^2$—related quantities are the following: “T(OIII)" is the electron temperature indicated by the predicted [OIII] 5007/4363 ratio in the low-density limit. This number is meaningless for densities near or above the critical density of the [O III] lines. “T(Bac)" is the hydrogen temperature resulting from the predicted Balmer jump and H$\beta$. “T(Hth)" is the same but for optically thin Balmer continuum and case B H$\beta$ emission. “t2(Hstrc)" is the structural H II $t^2$. The entries “T(O3-BAC)" and t2(O3-BC)" are the mean temperature and $t^2$ resulting from the standard analysis of the [O III] and H I spectra (Peimbert, 1967). Finally “t2(O3str)" is the structural $t^2$ over the O2+ zone. Only the structural $t^2$s are meaningful for high densities. This section was developed in association with Jim Kingdon, and Kingdon and Ferland (1995) provide more details.

CHAPTER 1. OUTPUT

The next lines give some information concerning grains if these were included in the calculation. These lines give the mean temperature, drift velocity, and potential, for all of the grain populations included in the calculation. An asterisk will appear to the right of the name of any species with quantum heating included. In this case the mean temperature is weighted by $T^4$.

The last line gives some information related to the grain abundance and optical properties. The first number is the dust to gas ratio by mass. The next two are the total visual extinction per unit hydrogen column density for a point and extended source. These are different because of the different effects of forward scattering (AGN3 section 7.6). Next comes the ratio of total to selective extinction. The line ends with $A_V$ for both an extended and point source.

1.10.6 Optical depths

Contin Optical Depths: COMP: 1.07e-03 H-: 1.90e-04 R(1300): 4.53e-02 H2+: 1.12e-06 Pfa:1.55E+02 Pa: 7.89e+02 Ba: 3.98e+03 Hb: 5.31e+02 La: 1.07e+04 1r:1.151E+05 4.:4.382E+06

Line Optical Depths: 10830: 8.12e+02 3889: 3.49e+01 5876: 1.91e-04 7065: 2.62e-05 2.06m: 1.29e-02 21c: 5.29e-01

The first two lines give the continuum optical depths at various energies. These are the total optical depths, including the correction for stimulated emission, and will be negative if maser action occurs. All opacity sources are included. The labels, and their interpretation, are as follows.

COMP is the Thomson scattering optical depth. “H-” is the optical depth at the wavelength where the negative hydrogen ion has its greatest maximum cross section. “R(1300)” is the optical depth due to Rayleigh scattering by H0 at 1300Å. “H2+” is the optical depth at the dissociation threshold of the molecular hydrogen ion. “Pfa” is the optical depth at the wavelength of the Pfund $\alpha$ transition (5-4).

The next line gives total continuous optical depths at the energies of various hydrogen and helium ionization edges and mean line optical depths\(^3\). These are evaluated at the energies of the Paschen $\alpha$, Balmer $\alpha$ and $\beta$, and L$\alpha$ lines, and the ionization edges of hydrogen, atomic helium, and the helium ion.

The third line gives optical depths of some He I lines. These are computed with a full model of the He0 atom (Porter et al., 2005).

\(^3\)Line center optical depths were reported through version C10. Mean line optical depths are now given, although the code works with line center optical depths internally.
Hydrogen and helium optical depths in continua and $\alpha(n \rightarrow n - 1)$ transitions follow. The first block of lines are the optical depths assumed at the start of the present iteration and the second block gives the newly computed total optical depths. Negative optical depths indicate maser action. For each of the pairs the first block is the optical depth at thresholds of levels of hydrogen. The optical depths in the $\alpha(n \rightarrow n - 1)$ transitions of hydrogen or helium follow.

### Line Optical Depths:

- $21830$: $3.52 \times 10^1$
- $3889$: $1.51 \times 10^0$
- $5876$: $2.11 \times 10^{-8}$
- $7065$: $2.88 \times 10^{-9}$
- $2.06\mu$: $2.86 \times 10^{-5}$
- $21\alpha$: $5.35 \times 10^{-5}$

### Hydrogen lines:

- $H_1 1215\AA$: $5.15 \times 10^5$
- $H_1 1025\AA$: $8.26 \times 10^4$
- $H_1 972\AA$: $2.87 \times 10^4$
- $H_1 949\AA$: $1.35 \times 10^4$
- $H_1 937\AA$: $7.45 \times 10^3$
- $H_1 930\AA$: $4.56 \times 10^3$
- $H_1 926\AA$: $3.00 \times 10^3$
- $H_1 923\AA$: $2.08 \times 10^3$
- $H_1 920\AA$: $1.51 \times 10^3$
- $H_1 919\AA$: $1.12 \times 10^3$
- $H_1 918\AA$: $8.62 \times 10^2$
- $H_1 917\AA$: $6.75 \times 10^2$
- $H_1 916\AA$: $5.39 \times 10^2$
- $H_1 915\AA$: $4.37 \times 10^2$
- $H_1 915\AA$: $3.59 \times 10^2$
- $H_1 914\AA$: $2.99 \times 10^2$
- $H_1 914\AA$: $2.52 \times 10^2$
- $H_1 914\AA$: $2.14 \times 10^2$
- $H_1 914\AA$: $1.83 \times 10^2$
- $H_1 913\AA$: $1.58 \times 10^2$
- $H_1 913\AA$: $1.37 \times 10^2$
- $H_1 913\AA$: $1.20 \times 10^2$
- $H_1 913\AA$: $9.34 \times 10^1$

### Log10 Column densities (cm$^{-2}$)

- $H_{tot}$: 25.107
- $HII$: 21.167
- $HI$: 21.830
- $H-$: 12.687
- $H_2g$: 24.806
- $H_2\ast$: 16.421
- $H_2+$: 11.203
- $HeH+$: 11.485
- $H_3+$: 13.820
- $CH$: 17.799
- $CH+$: 12.136
- $OH$: 14.764
- $CH_2$: 17.544
- $HCO+$: 15.394
- $CH_3$: 17.563
- $H_2CO$: 17.529
- $H_2O$: 17.459
- $H_2O+$: 11.049
- $O_2$: 17.909
- $CO$: 21.489
- $CO+$: 10.423
- $H_2$: 21.830
- $H_2+$: 11.203

This lists the column densities (cm$^{-2}$) of some atoms, ions, and molecules. The first number “Htot” is the total column density of hydrogen in all forms (including atoms, ions, and molecules). The following two numbers are the column densities in H$^+$ and H$^0$. The last four numbers are column densities in four ions and molecules (H$^-$, H$_2^+$, H$^*_2$, H$^+_3$, and HeH$^+$). The remaining
lines give column densities in various molecules. Molecules with names ending in “grn” are solids that have condensed onto grain surfaces.

The next block gives column densities in atoms and ions of the heavy elements. For hydrogen the last number is the H\_2 column density. Column densities within certain excited states of the heavy elements, listed in Table 8.1 on page 76, are also printed. The label gives the element, ionization stage, and level within the ground term. These upper levels are photoexcited by the so-called “level 2 lines”. Their pumping will not be included and excited state column densities will not be predicted if the level 2 lines are disabled with the **no level 2 lines** command.

</tbody>
</table>

The next blocks of output give the log of the mean ionization, averaged over volume, area (if the model is spherical), and over radius. The volume-averaged ionization fraction for ion \( i \) of element \( a \) is given by

\[
\langle n^i_a \rangle_{vol} = \frac{\int n^i_a f(r) r^2 dr}{\int n_a f(r) r^2 dr}.
\]  

the area average by

\[
\langle n^i_a \rangle_{area} = \frac{\int n^i_a f(r) r dr}{\int n_a f(r) r dr}.
\]

and the radius average by

\[
\langle n^i_a \rangle_{rad} = \frac{\int n^i_a f(r) dr}{\int n_a f(r) dr}.
\]

Where \( n_a \) is the total gas-phase density and \( n^i_a \) is the density in ionization stage \( i \). Similar blocks of information will give the mean ionization weighted by electron density and volume, area, or radius.

### 1.10.10 Final report

Cloudy ends: 196 zones, 1 iteration, 1 caution. ExecTime(s) 86.97

The code ends by listing the number of zones and iterations that were performed and the number of warnings and cautions that occurred. Next comes the elapsed wall-clock time [s]. The last line will say “Cloudy exited OK” if the calculation is successful.
Chapter 2

OBSERVED QUANTITIES

2.1 Overview

This section describes how to convert the quantities actually used or predicted by CLOUDY into commonly observed ones.

2.2 Intensities of various continua

2.2.1 Incident radiation field

The incident radiation field is the light striking the cloud. The main printout gives the intensity of the incident radiation field with the label “Inci”. The total continuum [units erg s\(^{-1}\) or erg cm\(^{-2}\) s\(^{-1}\)] integrated over all energies is given with this label and a wavelength of 0. The incident radiation field is also evaluated at two wavelengths, 4860 Å and 1215 Å, as \( \lambda F_\lambda \) or \( v F_v \), [units erg s\(^{-1}\) or erg cm\(^{-2}\) s\(^{-1}\)].

The save continuum command will produce a file that contains the entire incident radiation field.

These entries will not be included if the aperture command is in effect.

2.2.2 The radiation field at specific wavelengths

The intensity of the diffuse radiation field that is emitted or reflected by the cloud is not normally included in the main output. The print continuum command will include this radiation field in the emission-line printout at a series of energies. These have units \( \lambda F_\lambda \) or \( v F_v \). See the discussion of the print continuum and set nFnu commands in Part 1 for further details. You can easily add more continuum points using the set nFnu add command, also described in Part 1.

These entries will not be included if the aperture command is in effect.

2.2.3 The radiation field integrated over a range of wavelengths

The emitted radiation field integrated over a series of wavelength bands is included in the main printout. The file continuum_bands.ini in the data directory specifies a series of wavelength
bands. Table 9.1 on page 94 lists the default bands. The label and wavelength that are printed in the emission-line output are given in the first two columns of that table. The code will integrate over these bands to find the total radiated energy and report this in the main printout. The continuum_bands.ini file can be edited to change the number of bands or their detailed properties.

This gives the total emission that occurs over the band and includes the incident radiation field and both line and continuum diffuse emission. Under many circumstances the radiation field within a band may be dominated by the incident field. The code can also report the emissivity in any of the emission quantities given in the main printout. For these continuum bands the emissivity will only be the diffuse emission from the cloud and will not include the incident field.

These entries will not be included if the aperture command is in effect.

2.3 Emission-Line Equivalent Widths

The equivalent width of an emission or absorption line is the number of Angstroms of the continuum that is equivalent to the energy in the line. It is defined as

\[ W_\lambda = \int \frac{F^c_\lambda - F^l_\lambda}{F^c_\lambda} d\lambda \approx -\lambda \frac{F_{\text{line}}}{\lambda F^c_\lambda} \]  (units of \( \lambda \))

where the fluxes are in the incident continuum \( (F^c_\lambda) \) and the line \( (F_{\text{line}}) \). By this convention the equivalent width of an emission line is negative.

The code’s output can be used to predict a line’s equivalent width. The previous section describes several of the radiation fields that are predicted. The code prints the intensity or luminosity of all lines and continua and the intensity of each relative to a normalization line.

The ratio of a line to continuum intensity or luminosity will be the dimensionless ratio \( F_{\text{line}} / \lambda F^c_\lambda \), part of the last term in equation 2.1. The line equivalent width is this ratio multiplied by the wavelength where the continuum is evaluated. For instance, you could trick the code into printing the relative intensities of the lines as an equivalent width relative to the incident radiation field at 1215 Å by including the command

normalize to ‘‘Inci’’ 1215 scale factor = 1215

This has two effects. It gives the intensities relative to the incident continuum at 1215 Å and multiplies this by the continuum wavelength in Angstroms, producing the rightmost ratio in equation 1.

A covering factor will complicate this slightly. (Covering factors are defined in the section Definitions in Part I of this document and in Section 5.9 of AGN3.) In the luminosity case partial coverage of the source is taken into account with the covering factor command and the luminosities are correct for this coverage. The ratio of line to continuum given in equation 2.1 will represent what is observed. In the intensity case the line intensity is given per unit area of cloud no matter what covering factor is specified. In this second case the ratio in equation 2.1 must be scaled by the covering factor.
2.4 Emission-Line Asymmetries

The inward fraction of the total emission of each line is always predicted by the code. It is not reported by default. Many lines are significantly inwardly beamed and this can lead to emission-line asymmetries if the envelope is expanding. The inward part of the lines will be printed if the print line inward command is entered. Note that the effects of this line beaming are very geometry dependent.

2.5 Surface Brightness

CLOUDY will normally predict a line’s intensity as $4\pi J$, the intensity radiated into $4\pi$ sr by a unit area of cloud, with units erg s$^{-1}$ cm$^{-2}$. Observations of resolved sources often measure the surface brightness, with units erg s$^{-1}$ cm$^{-2}$ arcsec$^{-2}$ or s$^{-1}$ cm$^{-2}$ sr$^{-1}$. Be careful! Some workers may report surface brightness with units erg s$^{-1}$ cm$^{-2}$ arcsec$^{-2}$ sr$^{-1}$. Remove the sr$^{-1}$ before continuing by multiplying by $4\pi$.

To obtain the predicted surface brightness we must divide the intensity $4\pi J$ by the number of square seconds of arc in $4\pi$ sr or the number of sr in $4\pi$ sr. One radian is $360/2\pi = 57.29578$ degrees, so 1 sr is $(180/\pi)^2 = 3282.806$ degree$^2$. There are $(60 \times 60)^2$ square seconds in a square degree, so there are $5.3464 \times 10^{11}$ square arc seconds in $4\pi$ sr. The surface brightness (per square second of arc) is the intensity $4\pi J$ multiplied by the inverse of this, or $1.8704 \times 10^{-12}$ arcsec$^{-2}$. The surface brightness (per sr) is the intensity $4\pi J$ divided by $4\pi$.

Note that this is only correct for a line that is emitted isotropically, because the code predicts $4\pi J$ while an observer measures $I$ along a particular direction. (The code does predict the fraction of a line that is emitted from the illuminated face of the cloud.) This discussion is only formally correct if $I = J$.

There is a print line surface brightness command, described in Section 15.21.17 Print line surface brightness [arcsec] of Hazy 1 which will change the intensity into surface brightness units. By default the final units will then be erg s$^{-1}$ cm$^{-2}$ sr$^{-1}$, but the command has an arcsec keyword to specify the surface brightness in erg s$^{-1}$ cm$^{-2}$ arcsec$^{-2}$.

2.6 Flux to luminosity

The luminosity is the intensity of a line multiplied by the total area of the shell. For full coverage this is $4\pi r^2$ where $r$ is the radius of the shell. If the shell only partially covers the continuum source then this should be multiplied by the covering factor.

2.7 Flux at the Earth

If the distance to the object is specified with the distance command, and the luminosity case is predicted then the flux observed at the Earth will be predicted if the print flux at Earth command also appears.
2.8 Relative hydrogen line intensities

Hydrogen line intensities can be predicted with great precision when Case B applies. Ferguson and Ferland (1997) describe CLOUDY’s original hydrogen atom and Ferland et al. (2009) describe its current implementation. It gives good results for all reported lines. The number of reported lines can be increased to go higher in the H I model atom by using the atom H-like levels command. This gives better results at the expense of more compute time.

The accuracy of CLOUDY’s H I line emissivities is limited by the size of the model hydrogen atom that can be computed on the fly. The definitive calculation for hydrogen recombination is that of Hummer and Storey (1987) and Storey and Hummer (1995), who used a 1000 level atom with all l-levels explicitly considered (that works out to something like a million levels!). The code interpolates on their tables and includes their Case A and Case B predictions within the main printout. The test cases limit_case*.in in the test suite compare the code’s predictions with their Case B values.

The Hummer and Storey (1987) calculation is for Case B conditions, which assume that many processes are unimportant (see AGN3). Neglected processes include collisional excitation from the ground or first excited states, induced processes where the incident continuum causes the atom to fluoresce, and line transfer in all non-Lyman lines. Case B is often an excellent assumption for galactic nebulae such as planetary nebulae or H II regions. Case B is not valid for gas densities greater than \(10^6\) cm\(^{-3}\) or when X-rays are present. When any of these processes are important the predictions of CLOUDY’s model atom are more realistic than Case B predictions.

2.9 Helium line intensities

The code includes a model of the He\(^0\) atom that is applied all along the helium iso-electronic sequence. The model can have an arbitrarily large number of levels (Bauman et al., 2005; Porter et al., 2005; Porter and Ferland, 2007). The predictions become more exact as the number of levels is increased.

2.10 Line Intensities in a dusty cloud

Two sets of line intensities are printed in the main output. The first block of lines, with the title “Intrinsic Intensities”, includes all the physics of line formation, including destruction by background opacities such as grains or photoelectric absorption, but does not include the effects of absorption and scattering of the line from regions away from that were the line forms. This would be the spectrum you would observe after correction for reddening or line of sight extinction.

The second block of emission-line intensities, with the title “Emergent Intensities”, includes the effects of absorption and scattering from regions outside those where the lines form. The distinction is important for any cloud that has a large dust optical depth of A\(_V\), for instance, an H\(^+\) region on the surface of a molecular cloud.

There are two simple limits for dust extinction. If the simulation only includes the ionized region of a photoionized cloud then extinction of optical or IR lines will be very small. This is because the total optical depth across an H\(^+\) layer is \(\tau \leq 1\) at 912 Å (AGN3, Chapter 2). Grain
2.11 Continuum pumping contribution to line intensities

Continuum pumping or fluorescence is included for all lines. The contribution is only explicitly reported if the `print line pump` command is entered. Whether or not this contribution actually adds to the observed line emission depends on the geometry. Continuum pumping increases the line emission if no related continuum absorption occurs. This will be the case if the continuum source is either not observed or not covered by absorbing gas. If absorbing gas covers an observed continuum source then the situation is like the P Cygni problem, and pumping may not increase the net intensity of the line at all (the absorption component will have the same equivalent width as the associated emission). The printed line intensity includes this contribution unless the `no induced processes` command is entered. (The `no induced processes` command has many other
effects and so should only be used as a test.)

The output produced by the save continuum commands does not include the pumped part of the line contribution. This is correct if the continuum source is included in the beam, but is not if only the gas is observed.

2.12 Column densities

The column densities of all constituents are printed at the end of the calculation. Column densities within many excited states are also printed. The excited states are identified with a ‘*’. The table that accompanies the description of the cdColm command (see Table 8.1 on page 76 above) identifies the various labels.

2.13 A synthetic spectrum

A table of emission-line intensities is part of the normal output. Sometimes a synthetic spectrum, rather than a table, is desired. Very coarse spectra can be generated with the save continuum or save spectrum commands, but a detailed synthetic spectrum is not the main purpose of this output.

It is best to save the emission-line spectrum and then post-process this data using your own software. Then blends of lines can be synthesized at any spectral resolution desired. The spectrum can be save two ways. The main block of emission-line intensities in the final printout can be printed as a single column, which can be sorted by intensity or wavelength (by using options on the print lines command in Section 1 of this document). The save spectrum command includes a set of all lines with non-zero intensities. Write a small program or script to read these tables and create a final synthesized spectrum.

2.14 Line profiles

The observed line profile can be predicted by integrating the emissivity of the line over the computed structure while taking the local velocity structure into account. The emissivity is obtained with the save lines emissivity command, described in Part 1 of this document. This gives the net emission, with units erg cm\(^{-3}\) s\(^{-1}\), emitted by a unit volume of gas and emergent from the cloud surface. The total emission is the integral of the emissivity. An integral over radius will give the line intensity \(4\pi J\) while an integral over volume will give the luminosity.

The observed profile will depend on the velocity field at each point in the integration. For static models this will be the Voigt function at the local temperature and microturbulence. For a dynamical model it will include bulk motion of the gas.
Chapter 3

LIMITS, ASSUMPTIONS, AND RELIABILITY

3.1 Overview

This section outlines some of the assumptions and limits that define the range of validity of CLOUDY. The code is designed to be autonomous and self-aware, and to check that these limits are not exceeded during a calculation. This self-checking is a central feature of the code since it is designed to be used to compute large grids with thousands of models, where the examination of individual results would not be possible. CLOUDY should print a warning after the last zone results if any aspects of the calculation are in doubt.

3.2 Time steady

CLOUDY does not assume that the gas is in equilibrium. In most cases it does, however, assume that atomic processes occur on timescales that are much faster than other changes in the system, so that atomic rates have had time to become time-steady. It is possible to follow time-dependent conditions or an advective flow.

In practice most calculations assume that the cloud is old enough for atomic processes to have become time steady. The age command (described in Part I of this document) should be used to specify the age of the cloud. The code will then confirm that the time-steady assumption is valid by comparing the system’s age with a host of rates and timescales, and will generate a warning if the environment is not time-steady.

Various time scales characterize the approach to equilibrium of an ionized gas (see Spitzer, 1962, and Ferland, 1979 for a specific application). Generally, for an ionized gas with nebular temperatures \( T \sim 10^4 \) K, the longest is the H\(^+\) recombination time scale,

\[
T_{\text{rec}} = \frac{1}{\alpha_A (T_e) n_e} = 7.6 t_4^{0.8} n_4^{-1} \text{ years} = 0.66 t_4^{0.8} n_9^{-1} \text{ hours}
\]  

(3.1)

where \( t_4 \) is the temperature in units of \( 10^4 \) K, \( n_9 \) is the electron density in units of \( 10^9 \) cm\(^{-3}\), and case A recombination is assumed (AGN3).
The time scales are far more ponderous in molecular regions. Generally among the longer of the
time scales is the time to form H$^-$, an important pacesetter for H$_2$ formation in grain-free
environments. This time scale is roughly given by

$$T_{molecule} = \frac{1}{\alpha_{\text{rad}}(T_e) n_e} = 0.3 t_3^{-0.8} n_9^{-1} \text{ years}$$  \hspace{1cm} (3.2)$$

where $t_3$ is the temperature in units of 10$^3$ K.

If the age of the cloud is not long enough for atomic processes to become time steady then a
time-dependent calculation should be done. If the gas flow is fast enough for advection to add
significant terms to the statistical equilibrium equations then a wind calculation should be
performed. Commands for these simulations are described in Chapter 13, \textit{DYNAMICAL &
TIME-DEPENDENT CALCULATIONS}, in Hazy1.

3.3 Atomic and molecular database

This section outlines some of the atomic and molecular physics issues that affect the reliability of
numerical simulations of nebulae. These uncertainties were extensively discussed in the
Lexington Plasma 2000 meeting (ASP Conf series 247, \textit{Spectroscopic challenges of photoionized
plasmas}, Gary Ferland & Daniel Savin, editors) and they underscore the importance of atomic and
molecular physics for the interpretation of astrophysical spectroscopy.

3.3.1 Collisonal processes

By its nature, the electron temperature of a photoionized gas is low compared with the ionization
temperature of the mixture of atoms and ions, as defined by the Saha equation (if the two were
comparable, the gas would be collisionally ionized). Because of this, the rate coefficients
describing collisional effects, such as the production of cooling emission lines, are often
dominated by the cross sections near threshold. This is where laboratory experiments are difficult
and \textit{ab initio} quantum theory must often be used. As a result, the collision strengths undergo
constant revision, towards better and more reliable values.

To cite one extreme example, the collision strength for transitions within the $^3P$ ground term of
Ne$^{+4}$ underwent three revisions between 1984 and 1991, each by a factor of 10, because of
theoretical uncertainties in positions of autoionizing states with unknown energies (Lennon and
Burke, 1991). The intensities of all emission lines can be affected by major changes in the atomic
data for only one line for some conditions. This is because (in this case) the infrared fine structure
lines of Ne$^{+4}$ can be important coolants in low-density high-ionization gasses such as planetary
nebulae, and changing their cooling rate alters the thermal structure of the entire nebula. Such
changes often give even models of time-steady objects such as planetary nebulae certain
time-dependent characteristics.

At present, there are fairly reliable calculations of collision strengths and transition probabilities
for the majority of the strong optical and ultraviolet lines in moderate ionization nebulae. A series
of papers by Oliva and collaborators (see Oliva et al., 1996 and van Hoof et al., 2000) outline
observational evidence concerning accuracies in collision strengths of moderate ionization far
infrared lines.
Some strong cooling lines of high ionization species do not have accurate collision rates. As an example, few of the “level2” lines included in the code have real collision strengths. Various forms of the “g-bar” approximation are used for those lines that do not have accurate collision rates.

### 3.3.2 Photoionization cross sections

The photoionization cross-section database has undergone a dramatic improvement with the completion of the Opacity Project (Seaton, 1987) and its fitting with analytic approximations (Verner et al., 1996). These are the photoionization cross sections used by CLOUDY and they should be as accurate as 10%. All inner shell multi-electron processes are included (Kaastra and Mewe, 1993) using distorted wave cross sections (referenced in Verner et al.). This part of the database is in fairly good shape, although greater accuracy is always desired.

“Fano profiles”, due to autoionization resonances, appear as large changes in photoionization cross section that occur over a narrow range of energy, are averaged over, as described by Verner et al. Their positions are not accurately known, and they could make a difference if sharp spectral features occur in the stellar continuum at the position of a resonance. The photoionization rate could be changed dramatically in this case. Experimental data would be needed to upgrade the photoionization data base to include Fano profiles.

### 3.3.3 Recombination rate coefficients

Recombination from closed shell species is accurately known (Verner and Ferland, 1996) since these are dominated by radiative recombination. Reliable dielectronic recombination coefficients do not now exist for most other stages of ionization. Currently there is no theory that can reproduce the best experiments (Savin et al., 1999). For these, CLOUDY uses the guestimates described in Part I of this document. This is clearly the greatest single gap in the atomic data base today. Savin (2000) shows an example where this uncertainty has a direct impact on cosmological studies.

### 3.3.4 Charge transfer

The rate coefficients for charge transfer are another uncertainty in the atomic and molecular database. This process is sometimes the dominant neutralization mechanism for singly or doubly ionized heavy elements. At present many charge exchange rate coefficients are the result of Landau-Zenner calculations using semi-empirical potential curves (Kingdon and Ferland, 1996, Kingdon and Ferland, 1999). These are thought to be no more accurate than a factor of three. Even the best quantal calculations are not thought to have an accuracy much better than 50 percent. Unpublished tests suggest that these uncertainties affect some line intensities at the $\sim 20\%$ level, and a few by more than this.

### 3.4 Continuous opacity

All significant continuous opacity sources are treated for the energy range considered by the code, $1.001 \times 10^{-8}$ Ryd to $7.354 \times 10^{6}$ Ryd. These opacity sources include inverse bremsstrahlung,
CHAPTER 3. LIMITS, ASSUMPTIONS, AND RELIABILITY

grains (when present), H\(^-\) absorption, electron scattering, the damping wings of strong resonance lines (i.e., Rayleigh scattering), pair production, photoelectric absorption by the ground and excited states of all ions of the lightest 30 elements, and photoabsorption by molecules. This treatment should be adequate as long as the optical depths to electron scattering are not large. CLOUDY is not now designed to simulate Compton-thick regimes. (A warning will be issued after the last zone calculation if the nebula is very optically thick to electron scattering.)

3.5 Temperature range

CLOUDY assumes that the electrons are non-relativistic, which limits it to temperatures below roughly 10\(^9\) K. CLOUDY goes to the Compton temperature of the radiation field to great accuracy in the limit of very high levels of ionization for blackbody radiation fields with temperatures between 2.8 K and 1.001 \times 10^{10} K. There is no formal lower temperature limit to its validity. Note that very cold gas is rarely in steady state, however, because of the very slow collision rates. Similarly, the collision timescales in very hot gas \(T \gg 10^8\) K are not rapid enough to ensure that the electrons and ions have the same temperature, or that heating - cooling balance has become time steady (Johnson and Quataert, 2007). Electron-ion decoupling is not now included.

The range of validity of the code is approximately from 10 K to 10\(^9\) K. Temperatures outside this range can still be treated, although with greater uncertainty. The code will not permit temperatures below 2.8 K or above 1.001 \times 10^{10} K.

3.6 Density range

There is no formal lower limit to the density that CLOUDY can treat. The set of heavy element fine structure lines, which dominate cooling at low densities, is complete for astrophysically abundant elements, and fine structure line optical depths, continuum pumping, and maser effects are fully treated.

There is no formal high-density limit, although the simulation is less complete at high \(n \approx 10^{10} \text{ cm}^{-3}\) densities. Line radiative transfer processes are fully treated with either escape or Sobolev approximations (see Kalkofen, W., 1987 and Avrett and Loeser, 1988) and collisional-radiative ionization processes for excited levels of the heavy elements are treated. All species of H-like and He-like isoelectronic sequences are treated as many-level atoms, including all of the physical processes that allow the approach to LTE (see, for example, Mihalas, 1978). Tests with a hydrogen density of 10\(^19\) cm\(^{-3}\) show that the hydrogen and helium atoms and the hydrogen molecules go to LTE at high densities. They go to strict thermodynamic equilibrium when exposed to a true black body. The treatment of Stark broadening for hydrogen lines follows Puetter (1981), so line radiative transfer is treated correctly (in the context of the escape probability formalism) for densities above \(\sim 10^{10} \text{ cm}^{-3}\).

The treatment of the other 28 isoelectronic sequences is presently not as complete as the H and He-like sequences. Three-body recombination is included as a general recombination process, so the treatment of these elements is approximately correct at high densities.

CLOUDY has been tested at densities of 10\(^{-8}\) cm\(^{-3}\) and 10\(^19\) cm\(^{-3}\) on 32-bit machines. The numerical (not physical) limit to the density will actually be set by the limits to the range of the
floating point numbers allowed by the machine in use. The physics incorporated in the code imposes no lower limit to the density. The physical high-density limit is roughly \(10^{15} \text{ cm}^{-3}\), and is set by the approximate treatment of three-body recombination - collisional ionization for the heavy elements.

### 3.7 Radiative transfer

Several tests presented in the test suite show that the continuum transfer methods are in excellent agreement with known exact results.

Line intensities are predicted with stellar atmosphere conditions in mind. Radiative transfer effects, including continuum pumping and possible maser emission, are treated. Nebular approximations, such as the approximation that all atoms are in the ground state, are not made. Collisional effects, including excitation and de-excitation, continuum fluorescence, recombination, etc, are all included as general line excitation mechanisms. The treatment of level populations is designed to go to LTE in the high particle or photon density cases.

The transfer of subordinate lines, those where both upper and lower level of the transition occur in excited state, of the H-like and He-like iso sequences at high \(n \gg 10^{10} \text{ cm}^{-3}\) densities is a concern. Resonance lines should be fine.

### 3.8 Reliability

Several issues affect the general question of the reliability of the code. The first is the effects of the bugs that surely must exist in a code the size of CLOUDY. I have seldom found bugs in sections of the code older than roughly two to three years. Younger sections of the code sometimes contain bugs that only manifest themselves in exceptional situations. The issue of reliability in the face of complexity will increasingly be the single major problem limiting the development of large-scale numerical simulations (Ferland, 2001). New methods of writing code will have to be developed if we are to take full advantage of the power of future machines. Machines are getting faster more quickly than people are getting smarter.

The second issue is the validity of the numerical methods used to simulate conditions in the plasma. Fundamental uncertainties arise for cases where the density is high \(n \gg 10^{10} \text{ cm}^{-3}\). The line radiative transfer techniques used by CLOUDY are approximate (see the discussion by Avrett and Loeser, 1988). Unfortunately, no definitive calculation now exists for the complete non-LTE equilibrium and line emission for an intermediate density \(\sim 10^{13} \text{ cm}^{-3}\) cloud. For less extreme conditions \(n < 10^{10} \text{ cm}^{-3}\) nebular approximations are valid.

Test cases that are designed to exercise the code in well-posed limits and for certain standard nebulae are in the test suite. The code is well behaved and agrees with predictions of similar codes in these limits. The discussion presented in Ferland (1995) and Péquignot et al. (2001) suggests that 10% accuracy can be reached for the intensities of the stronger lines.

The uncertainties can probably best be judged by looking at both the dispersions among the various photoionization calculations presented in Ferland (1995) and Péquignot et al. (2001), and by the changes in the test suite. Much of the dispersion is due to improvements in the atomic database.
There can be little better way to close a discussion of reliability than to quote the warning included in the description by (Kurucz, 1970, see page xiii) of ATLAS5, a code more than an order of magnitude smaller than CLOUDY:

**WARNING**

“There is no way to guarantee that ATLAS5 does not contain errors. In fact, it is almost certain that it does, since the code is so long… We also point out that the computation of a model atmosphere should be considered a physical experiment. The program may not be able to calculate a model for conditions that do not occur in real stars or for conditions that violate the initial assumptions on which the program is based.”

### 3.9 The future

The eventual goal is for CLOUDY to give reliable results for all extremes of conditions between and including the intergalactic medium and stellar atmospheres. I estimate that the code is now well over halfway complete.

Current work centers on taking advantage of parallel machines. Once finished, we will be able to use this additional computational power to improve the treatment of hydrodynamics, line radiative transfer, and higher-order dimensionality.
Chapter 4

THE CONTINUUM

4.1 Overview

Under most circumstances the radiation field produced by the central object is the only source of heat and ionization. This section describes how this continuum is treated.

4.2 Attenuation of the incident continuum

In an open geometry scattering attenuates the incident continuum as

\[ I = I_o (1 + 0.5 d \tau_{\text{scat}})^{-1}. \]  \hspace{1cm} (4.1)

Scattering does not affect the continuum in a closed geometry. Absorption attenuates the incident continuum as

\[ I = I_o \exp(-d \tau_{\text{abs}}). \]  \hspace{1cm} (4.2)

for both geometries.

4.3 Recombination equilibrium

4.3.1 On-the-spot approximation

A modified version of the “on-the-spot” (OTS) approximation is used in the treatment of sources of diffuse ionizing radiation when the diffuse OTS command is used. Were no other opacity sources present, then, for a closed geometry that is optically thick in the Lyman continuum, all recombinations of hydrogen or helium to the ground state would produce ionizing photons. Other atoms of the recombined species would quickly absorb these. In this case OTS is an excellent approximation (van Blerkom and Hummer, 1967; Baessgen et al., 1988). However, other opacity sources are present, and these compete in absorbing protons produced by recombinations, making the recombination process more efficient than the OTS approximation would suggest.

The recombination coefficients are modified by the presence of all other opacity sources, such as grains, free-free or H⁻ absorption, and the heavy element opacities, in the following manner. The net effective recombination rate coefficient (cm³ s⁻¹) to level \( n \), \( \dot{\alpha}(T_e,n) \), is written in terms
CHAPTER 4. THE CONTINUUM

of the spontaneous radiative recombination rate coefficient $\alpha(T_e, n)$ and the opacities (cm$^{-1}$) $\kappa_n$ and $\kappa_o$ for the level $n$ and other opacity sources respectively, as

$$\hat{\alpha}(T_e, n) = \alpha(T_e, n) \left\{ P_c(n) + [1 - P_c(n)] \left( \frac{\kappa_o}{\kappa_o + \kappa_n} \right) \right\}, \quad (4.3)$$

where $P_c(n)$ is the continuum escape probability. In general, $P_c(n)$ varies between 0 and 0.5 for an optically thick open geometry (see, for example Davidson, 1977), $P_c \sim 1$ if the gas is optically thin, and $P_c \sim 0$ for ground states if the gas is optically thick and the geometry is closed. All computed opacity sources are included in $\kappa_o$.

These recombination continua produce a flux of local on-the-spot photons, $\varphi_{OTS}$ (cm$^{-2}$ s$^{-1}$). The OTS photoabsorption rate $\Gamma_{OTS}$ (s$^{-1}$), used to determine the ionization or heating rate for the gas or grain constituents, is then $\Gamma_{OTS} = \alpha_\nu \varphi_{OTS}$ where $\alpha_\nu$ is the absorption cross section at frequency $\nu$. The OTS flux is related to the spontaneous recombination rate coefficient by

$$\varphi_{OTS} = \alpha(T_e, n) n_e n_{ion} \left[ \frac{1 - P_c(\tau)}{\kappa_o + \kappa_n} \right] \text{ cm}^{-2} \text{ s}^{-1} \quad (4.4)$$

where $n_{ion}$ is the density of the ion. These are stored in the vectors $otscon$ and $otslin$, which map one-to-one onto the vectors $flux$ and $anu$.

4.3.2 Outward only approximation

A composite “outward-only” (Tarter, 1967) –“on-the-spot” approximation is used in the treatment of sources of diffuse ionizing radiation when the diffuse outward command is used. This is the default assumption. The escaping radiation is then propagated in the outward direction (all for the spherical case, and half for an open geometry).

4.4 Continuous opacities

The cloud is divided into a large number of concentric shells (zones) and the attenuated and diffuse continua and physical conditions are then determined within each.

The main opacity sources in the ultraviolet continuum are generally photoelectric and free-free (inverse bremsstrahlung) absorption, grain opacity, electron scattering (of both bound and free electrons), and the damping wings of Lyman lines (Rayleigh scattering). The main reemission mechanisms are generally free-free (bremsstrahlung), grain emission, free-bound, and two-photon emission. Grains are not present by default but can be added as an option. Continuous absorption and reemission by all ground states, and many excited states, of all ionization stages of the 30 elements in the calculation are explicitly included. Great care is taken to ensure that each absorption mechanism is balanced by a reemission process, and vice versa, so that energy balance in the strict thermodynamic equilibrium limit can be achieved.

4.4.1 Total opacity arrays

Total absorption opacities (cm$^{-1}$) are stored in the vector $opac$. Total scattering opacities (cm$^{-1}$) are stored in $scatop$. The opacities are evaluated in routine $ConvIonizeOpacityDo$ and are within the $opac$ structure (defined in $opacity.h$).
4.4.2 Cross-section array

*Storage.* The cross sections per particle (cm$^2$) for individual species (atoms, ions, molecules, etc) are stored within the array OpacStack, a stack array with a single dimension. These cross sections are evaluated when the code is initialized in routine OpacityCreateAll.

*Array indices.* Each species has an associated array index that defines the offset between the origin of OpacStack, the frequency array anu, and the opacity at the threshold. If this offset has the name ioff, for instance, then the cross section at threshold will be given by array element OpacStack[ioff]. If ip is the index to the threshold energy within anu, then the array index to the cross section at energy $i$ will be $i - ip + ioff$.

*Individual cross-sections.* The function csphot returns the cross section at a specific frequency for any species. It has three arguments, 1) the pointer to the frequency in anu where the cross section is to be evaluated, 2) the pointer to the threshold for the species, and 3) the ioff offset described above. All are integer variables.

4.4.3 Photoionization rates

Photoionization rates (units s$^{-1}$) can be computed by several functions. Which is used at a particular time is determined by circumstances.

**GammaK** This computes the photoionization rate with allowance for an arbitrary fluorescence yield. This routine is a major pacemaker for the code since it is used to evaluate the continuum rates in the majority of the cases. The photoionization rate is given by

$$\Gamma_n = 4\pi \int_{v_0}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu \, d\nu \quad [s^{-1}].$$

(4.5)

where $\alpha_\nu$ is the photoionization cross section [cm$^{-2}$]. The routine has three integer arguments, the anu pointers to the lower and upper energies and the offset to the opacity array ioff (described above).

**GammaPrt** This is a special version of GammaK that writes the step by step results of the integration on any open file. The output lists the product of the photon flux and the cross section, the photon flux, and the opacity.

**GammaBn** This is a special version of GammaK that is used when the correction for stimulated emission or induced recombination is important. The photoionization rate is given by

$$\Gamma_n = 4\pi \int_{v_0}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu \, d\nu \quad [s^{-1}]$$

(4.6)

and the rate for induced recombination and its associated cooling is computed as

$$\alpha (ind) = P^* n 4\pi \int_{v_0}^{\infty} \frac{J_\nu}{h\nu} \alpha_\nu \exp \left(-h\nu/kT\right) \, d\nu \quad [cm^3 \, s^{-1}].$$

(4.7)

where $P^*$ is the LTE population.

**GammaPrtRate** will print photo rates for all shells of an ion and element. It is called with three arguments, a file handle, followed by the ionization stage and element number on the C scale (0 for H or atoms, etc).
4.4.4 Attenuation within the zone

A correction must be made to account for the attenuation of the continuum across the zone (Netzer and Ferland, 1984). Assuming that the continuum varies across the zone as

\[ I(\nu, \delta r) / I_0(\nu) = \exp(-\kappa(\nu) f(r) \delta r) \]  

(4.8)

then the intensity averaged over a zone with thickness \( \delta r \) is

\[ \langle I(\nu, \delta r) / I_0(\nu) \rangle = 1 - \exp(-\kappa(\nu) f(r) \delta r) / \kappa(\nu) f(r) \delta r \]  

(4.9)

where \( \kappa(\nu) \) is the absorption opacity and \( f(r) \) is the filling factor. The coefficients giving this ratio as a function of energy are stored in the vector \( t_mn \), and are evaluated in routine \( radinc \). The continuum stored in \( flux \) is multiplied by these factors in the same subroutine.

4.4.5 Rayleigh scattering

Clouds with neutral hydrogen column densities greater than \( 10^{23} \text{ cm}^{-2} \) are optically thick to Rayleigh scattering at wavelengths near \( \text{L}_\alpha \), and this process is a major scattering opacity source at short wavelengths for grain-free environments.

Rayleigh scattering cross sections given by Gavrila (1967) are used, joined with expressions for the radiative damping wings of Lyman lines (Mihalas, 1978). For wavelengths longward of 1410 \( \text{Å} \) a power-law fit to Gavrila’s quantal calculations is used;

\[ \sigma_{\text{Ray}} = 8.41 \times 10^{-25} \epsilon^4 + 3.37 \times 10^{-24} \epsilon^6 + 4.71 \times 10^{-22} \epsilon^{14} \text{ cm}^2 \]  

(4.10)

where \( \epsilon \equiv /cR_\infty \) is the photon energy in Rydbergs. This fit is accurate to typically a percent, with occasional errors as large as 4 percent.

For wavelengths between 1410 \( \text{Å} \) and the Lyman limit, radiative broadening of the Lyman lines is assumed (Mihalas, 1978);

\[ \sigma_{\text{Ray}} = \sum_{i=2}^{4} \left( \frac{q_e^2 f_{1,i}}{m_e c} \right) \frac{\Gamma/4\pi}{(\nu - \nu_{1,i})^2} \text{ cm}^2 \]  

(4.11)

where \( \Gamma \) is the reciprocal lifetime of the upper level \( i \) and the sum is over the first four Lyman lines. This expression gives cross sections in excellent agreement with Gavrila (1967) for these wavelengths.

4.4.6 Free-free opacity

The main opacity source in the infrared-radio spectral region for many conditions is free-free opacity with a cross section given by

\[ \alpha_\nu(\text{ff}) = 3.69 \times 10^8 \bar{g}_{\text{III}}(\nu, T) f(r) \nu^{-3} T^{-1/2} \{1 - \exp(-h\nu/kT)\} \sum_A \sum_z \epsilon^{2} n_A^{+z} \text{ [cm}^{-2}] \]  

(4.12)
4.4. CONTINUOUS OPACITIES

Figure 4.1: Thermally averaged free-free gaunt factor. The gaunt factor is shown as a function of photon energy and temperature.

(see, for example, Mihalas, 1978). The sum is over all ions $n^{\pm z}$ of element $A$ and over all elements. The temperature averaged gaunt factor $\bar{g}_{III}(\nu, T)$ is taken from Hummer (1988) (see also Karzas and Latter, 1961) and are evaluated in routine gffsub that was originally written by D. Hummer.

This routine did not extend to energies that could be treated by asymptotic expansions of the gaunt factor. gffsub was modified by J. Ferguson to extend over the full temperature and energy range considered by CLOUDY, and later extensively rewritten by Ryan Porter. Figure 4.1 shows the gaunt factors as functions of photon energy and temperature.

4.4.7 Bound-free opacity

Continuum optical depths for photoabsorption from level $l$ are given by

$$d\tau_l(\nu) = \alpha_\nu(n) n_l [1 - \exp(-\hbar\nu/kT)/b_l] f(r) \delta r$$

(4.13)

where $b_l$ is the departure coefficient for level $l$ and $\alpha_\nu$ is the absorption cross section [cm$^{-2}$].
4.4.8 Plasma frequency

The plasma frequency, the energy where the index of refraction of an ionized medium goes to zero, is given by

\[ \nu_{pl} = \left( \frac{n_e q_e^2}{\pi m_e} \right)^{1/2} = 8.978 \times 10^3 \ n_e^{1/2} \ s^{-1} = 2.729 \times 10^{-12} \ n_e^{1/2} \ \text{Ryd} \quad (4.14) \]

An ionized gas will reflect the incident continuum for energies smaller than this. This shielding becomes important for the energy range considered by CLOUDY for electron densities greater than \( \sim 10^7 \text{cm}^{-3} \). For higher densities this process is treated by setting the intensity of the incident continuum to zero for energies below the plasma frequency, adding this portion of the incident continuum to the reflected continuum, and not allowing emission or absorption for any processes that occur below the plasma frequency.

4.4.9 Pressure lowering of ionization potential

The electric field of nearby charges in the continuum acts to lower the ionization potential. The amount by which it is lowered is determined by the electron density. Ryan Porter extended the code to consider all species treated with the iso-electronic model atoms.

4.5 Continuum range

The energy interval \( 1.001 \times 10^{-8} \ \text{Ryd} - 7.354 \times 10^6 \ \text{Ryd} \) is divided into a large number of energy cells with nearly logarithmically increasing widths.

4.6 The continuum mesh

4.6.1 Continuum mesh logic

The central frequencies of two cells are related by

\[ \frac{\nu_{i+1}}{\nu_i} = \exp(r) \quad (4.15) \]

where \( r \) is the resolution, \( \delta \nu / \nu \). Then the \( n^{th} \) cell energy is related to the first cell energy by

\[ \nu_n = \nu_0 \exp(nr). \quad (4.16) \]

The cell corresponding to energy \( \nu_n \) is then

\[ n = \frac{\log(\nu_n / \nu_0)}{r}. \quad (4.17) \]

4.6.2 Defining the continuum energy mesh

The array \( \text{anu} \) gives the energy of the center of each continuum cell, in Rydbergs. This energy scale is defined in routine \( \text{ContCreatePointers} \).
4.6.3 Changing the energy resolution of the mesh

The file `continuum_mesh.ini` contains ordered pairs of continuum energies and resolving powers (defined as $1/r$) that are read by `ContCreatePointers` to set the continuum mesh when calling `fill`. Change the contents of `continuum_mesh.ini` to change the resolution of the continuum mesh. The file explains how to do this.

If the energy resolving power is increased then the code will require more mesh points to cover the full continuum and will run more slowly, but the predicted continuum will have greater detail.

4.7 Continuum generation

The continuum is generated by the function `ffun`. `ffun` has a single argument, the energy in Rydbergs, and it returns the number of photons per unit area, time, and Rydberg, at that energy. `ffun` sums over all the specified continua and applies the appropriate normalization factors.

Another function, `ffun1`, evaluates each individual continuum, and is normally called only by `ffun`.

The units, and their conversion to other measures of the continuum, are given below. The photon flux density is:

$$\phi_\nu(\nu) = \text{ffun}(\nu) \left[ \text{photons cm}^{-2} \text{s}^{-1} \text{Ryd}^{-1} \right].$$  \hspace{1cm} (4.18)

This is stored in the photon array:

$$\text{flux}(v_i) = \phi_\nu(\nu) \delta v_i = \text{ffun}(v_i) \times \text{widflx}(v) \left[ \text{photons cm}^{-2} \text{s}^{-1} \right]$$  \hspace{1cm} (4.19)

where `widflx` is an array containing the width of each continuum bin. Finally, the energy flux density is given by

$$f_\nu(\nu) = \text{ffun}(\nu) h \left( \frac{\nu}{\nu_{912}} \right) \left[ \text{erg cm}^{-2} \text{s}^{-1} \text{Hz}^{-1} \right]$$  \hspace{1cm} (4.20)

and

$$\nu f_\nu(\nu) = \text{ffun}(\nu) h \left( \frac{\nu}{\nu_{912}} \right) \nu_{912} h \nu_{\text{Ryd}} \left[ \text{erg cm}^{-2} \text{s}^{-1} \right].$$  \hspace{1cm} (4.21)

4.8 Energy units; the Rydberg

Continuum energies are usually given in Rydbergs. The energy of level $n$ of a hydrogenic atom is given by

$$E_n = -\frac{R_H}{n^2}, n = 1, 2, 3, \ldots, \quad \text{[units of } R_H]$$  \hspace{1cm} (4.22)

where the Rydberg energy is given by

$$R = \frac{\mu q^4}{2\hbar^2} = \frac{\mu}{m_e} R_\infty$$  \hspace{1cm} (4.23)

and the reduced mass of the orbiting electron $\mu$ is related to the electron and nuclear mass $m_e$ and $m_{\text{nuc}}$ by

$$\mu = \frac{m_e m_{\text{nuc}}}{m_e + m_{\text{nuc}}} = \frac{m_e}{1 + m_e/m_{\text{nuc}}} \quad [\text{g}],$$  \hspace{1cm} (4.24)
(Friedrich, 1998). Note that as \( m_{\text{nuc}} \to \infty, \mu \to m_e \). This Rydberg energy \( R_H \) is smaller than the energy for an infinite mass nucleus \( R_\infty \) by the ratio \( \mu/m_e \). Using the 1998 CODATA revision of the fundamental constants (see Cohen and Taylor, 1987; Mohr and Taylor, 2000) the infinite mass Rydberg energy is given by

\[
R_\infty = \frac{m_e q_e^4}{2\hbar^2} = 13.605698 [\text{eV}] \quad (4.25)
\]

and

\[
\frac{R_\infty}{(2\pi\hbar c)} = 109737.315686 \text{ cm}^{-1} \\
\frac{R_\infty}{(2\pi\hbar)} = 3.28984196038 \times 10^{15} \text{ Hz} \\
\frac{(2\pi\hbar c)}{R_\infty} = 91.126732 \text{ nm} \quad (4.26)
\]

The ionization potential of hydrogen \( R_H \) is \( \mu/m_e \) or \( \sim 0.99946 \) times smaller than \( R_\infty \). ¹ We have

\[
R_H = 13.59842 \text{ eV} \\
R_H = 2.178728 \times 10^{11} \text{ erg} \\
(2\pi\hbar)/R_H = 91.176430 \text{ nm} \\
R_H = 109677.576 \text{ cm}^{-1} \quad (4.27)
\]

The difference between \( R_H \) and \( R_\infty \) is significant since it enters as the third power in the photon phase-space conversion factor \( 2\hbar \nu^3/c^2 \).

The Bohr radius is for an infinite mass nucleus is given by

\[
a_o = \frac{\hbar^2}{(m_e q_e^2)} = 0.5291772083 \times 10^{-8} \text{ cm}.
\]

\[
a = a_o / \mu
\]

In the “atomic units” system of measuring quantities lengths are given in terms of the Bohr radius and energies in “Hartree” units. One Hartree is twice the Rydberg energy.

¹\( R_H \) was the Rydberg unit used by CLOUDY before 1988.
Chapter 5

LINE ATOMIC PARAMETERS

5.1 Overview

Many atomic physics quantities describe how matter and light interact. This section goes over these quantities and how they are related to one another. The inter-relations between these quantities are described in most spectroscopy texts, at about the same depth as is given below. Hilborn (1982) gives a far more formal description, often tracing quantities back to basic E&M concepts. Highly recommended.

5.2 Spectroscopic notation

A great deal of confusion exists over the difference between the designation of a spectrum and an ion. “Atom II” denotes a spectrum, a collection of photons, while “Atom^+” denotes a baryon, the element “Atom” with a single electron removed.

Much of the notation in today’s atomic physics was developed in the second half of the 19th century. Physicists noticed that the spectrum of a gas would change dramatically when it was heated to high temperatures. They did not understand the reason why this happened, the electron had not yet been discovered, but they developed the notation that “Atom I” was the normal spectrum, this spectrum changed to “Atom II” when the gas was heated, and became the “Atom III” spectrum if heated still further. The “Atom II” spectrum was often called the “enhanced” spectrum of Atom. This is the reason why, in classical novae, the appearance of broad absorption lines of singly ionized species is called the “diffuse enhanced phase”.

The electron was discovered well after this notation had been developed. By the early 20th century it was understood that the “I” spectrum was produced by the atom, Atom^0. At high temperatures the first ion, Atom^+, formed and produced the “Atom II” spectrum.

During the first half of the 20th century astrophysicists mainly studied stellar absorption lines. This led to the commonly-used notation that the “Atom II” spectrum, for instance, measured Atom^+. It is unambiguously true that the equivalent width of an Atom II absorption line is proportional to the column density of Atom^+. However there is an ambiguity in emission lines. The Lα H i line can be produced by impact excitation of H^0 or by recombination of H^+. In both cases the line is an H i line, but H i is produced by either H^0 or H^+, depending on details.

To be unambiguously correct you should refer to Atom I or Atom II when discussing the
spectrum. When discussing a column density or particle density you should refer to the ion, as in Atom$^0$ or Atom$^+$. It is not correct to refer to the column density of H I. The L$\alpha$ H I emission line measures the column density of either H$^0$ or H$^+$, depending on whether the line forms by impact excitation or recombination. The notation is not ambiguous in absorption lines, which is probably why we have such confusion today. Be unambiguous and correct - use the right notation!

### 5.3 Line absorption

#### 5.3.1 Line optical depths

The optical depth for a transition $u \rightarrow l$, where $u$ and $l$ are the upper and lower levels, is given by

$$d\tau_{u,l} = \alpha_\nu (n_l - n_u g_l/g_u) \int f(r) \, dr \left[ \text{Napier} \right]. \tag{5.1}$$

Here $f(r)$ is the filling factor and $\alpha_\nu$ is the atomic absorption cross section [cm$^2$].

The term in parenthesis is the population [cm$^{-3}$] of the lower level, with a correction for stimulated emission. This term is the only place where stimulated emission enters in the radiative balance equations (Elitzur et al., 1983).

#### 5.3.2 Oscillator strengths

The oscillator strength $f$ is a dimensionless number of order unity that can be thought of as a correction factor to make the expression for a classical oscillator agree with the quantum mechanical value. Sections below relate the oscillator strength to other line parameters such as the absorption coefficient and the transition probability. The absorption ($f_{abs}$, called $f_{1,u}$ here) and emission ($f_{em}$, called $f_{u,l}$) oscillator strengths are related by

$$g_l f_{1,u} = -g_u f_{u,l} \tag{5.2}$$

where the $g$’s are the statistical weights. This product is symmetric, neglecting sign, and the code tries to use $gf$’s throughout. The convention is that emission lines have negative oscillator strength.

#### 5.3.3 Absorption cross section

The line-center absorption cross section [cm$^2$] is related to the dimensionless absorption oscillator strength $f_{1u}$ or $f_{abs}$ by

$$\alpha_\nu = \frac{\pi^{1/2} q_u^2 \lambda_{f_{1u}} \varphi_\nu(x)}{m_e c u_{Dop}} \varphi_\nu(x) = 0.014974 \lambda_{em} f_{1,u} \frac{\lambda_{em}}{u_{Dop}} \varphi_\nu(x) \quad \left[ \text{cm}^2 \right] \tag{5.3}$$

with the relative line displacement given by

$$x \equiv \frac{v - v_0}{\Delta v_{Dop}} \tag{5.4}$$

$\varphi_\nu(x)$ is the Voigt function, and $u_{Dop}$ is the Doppler velocity width (cm s$^{-1}$), the point where the line profile falls to 1/e of its peak. With this definition of the relative line displacement, the line profile due to thermal motions alone is $\exp(-x^2)$. Equation 5.3 is evaluated in routine $abscf$. 

5.4 The line profile function

5.4.1 Velocities in a thermal distribution

The distribution function for a Maxwellian velocity distribution is given by

\[
\frac{n(u) \, du}{n} = \frac{1}{\pi^{3/2}} \exp \left[ -\frac{u^2 m_A}{2kT} \right] \frac{m}{(2kT)^{3/2}} \frac{4\pi u^2 \, du}{u^3} \text{ [cm s}^{-1}] \tag{5.5}
\]

(Novotny, 1973; p 122). There are three mean speeds in a thermal velocity distribution. The most probable speed is the peak of the velocity distribution, with a value

\[
u_{\text{mean}}^2 = \frac{2kT}{m_A} \text{ [cm}^2 \text{s}^{-2}] \tag{5.6}
\]

This is found by setting the derivative of the distribution function to zero (Novotny, 1973, p 122). The velocity distribution function can be expressed in terms of the mean speed as

\[
\frac{n(u) \, du}{n} = \frac{1}{\pi^{3/2}} \exp \left[ -\frac{u^2}{\nu_{\text{mean}}^2} \right] \frac{4\pi u^2 \, du}{u_{\text{mean}}^3} \text{ [cm s}^{-1}] \tag{5.7}
\]

The average speed is obtained by averaging over this function and is given by

\[
u_{\text{average}}^2 = \frac{8kT}{\pi m_A} \text{ [cm}^2 \text{s}^{-2}] \tag{5.8}
\]

The thermal Doppler velocity width is the velocity averaged over the projected line of sight, given by (Novotny, 1973; p 204)

\[
u_{\text{th}}^2 = \frac{2kT}{m_A} \text{ [cm}^2 \text{s}^{-2}] \tag{5.9}
\]

This is the distance from line center where the line profile falls to \( e^{-1} \) of its central value. So it turns out that the most probable speed is equal to the Doppler velocity width.

The velocity dispersion \( \sigma \) is

\[
\sigma = u/\sqrt{2} \text{ [cm s}^{-1}] \tag{5.10}
\]

and appears in the Gaussian profile function as

\[
\phi(\delta u) = \exp \left( -\frac{\delta u^2}{2\sigma^2} \right). \tag{5.11}
\]

5.4.2 Micro vs macro turbulence

Micro-turbulence (hereafter, just turbulence) is due to any additional motions that occur over scales that are smaller than a photon mean free path. Micro-turbulence changes the line transfer since the line opacity is distributed over a broader range of velocities. Macro-turbulence is due to motion that occurs over such large scale lengths that they not change the optical depth through the emitting region. An example might be cloud orbital motions. The transfer within a cloud is not changed by its bulk motion and so would be considered macro-turbulence.
5.4.3 Line Widths

If a non-thermal micro-turbulent component of motions is present then equation 5.3, the total Doppler velocity width \([\text{cm s}^{-1}]\) including turbulence, is given by

\[
\begin{align*}
 u_{\text{tot}}^2 &= 2kT/m_A + u_{\text{turb}}^2 \quad \text{[cm}^2 \text{s}^{-2}] \\
 &\quad \text{as determined by the local kinetic temperature } T. \text{ Within the code the micro-turbulent velocity } u_{\text{turb}} \text{ is assumed to be zero unless it is reset with the } \text{turbulence} \text{ command.}^1
\end{align*}
\]

In \textit{GetDopplerWidth} the Doppler velocity width is evaluated as

\[
\begin{align*}
 u_{\text{Dop}} &= \sqrt{2kT/m_A + u_{\text{turb}}^2} \quad \text{[cm s}^{-1}]. \\
 &\quad \text{The atomic weight is in atomic mass units.}
\end{align*}
\]

The Doppler velocity width is related to the half width at half maximum by (Novotny, 1973, eqns 5-18; p 205)

\[
\begin{align*}
 \Delta u_{1/2} &= (\ln 2)^{1/2} u_{\text{Dop}} = 0.832555 u_{\text{Dop}} \quad \text{[cm s}^{-1}] \\
 \Delta u_{\text{FWHM}} &= 2(\ln 2)^{1/2} u_{\text{Dop}} \quad \text{[cm s}^{-1}].
\end{align*}
\]

5.4.4 The Doppler \(b\) parameter

Much of the literature refers to the Doppler \(b\) parameter. This is the Doppler velocity width or velocity dispersion with turbulence included, and is given by

\[
\begin{align*}
 b^2 &= u_{\text{Dop}}^2 = 2kT/m_A + u_{\text{turb}}^2 \quad \text{[cm}^2 \text{s}^{-2}]. \\
 &\quad \text{With these definitions}
\end{align*}
\]

\[
\begin{align*}
 b &= u_{\text{Dop}} = \Delta u_{\text{FWHM}} / \left[2(\ln 2)^{1/2}\right] \quad \text{[cm s}^{-1}].
\end{align*}
\]

5.4.5 Voigt function

Optical depths a relative displacement \(x\) away from line center are related to the line center optical depth \(\tau_0\) by

\[
\tau(x) = \tau_0 \varphi_v(x). \tag{5.18}
\]

The relative displacement is given by equation 5.4 above. The Voigt function is normalized to unity at line center and is approximately given by

\[
\varphi_v(x) \approx \exp(-x^2) + a/(\pi^{1/2}x^2). \tag{5.19}
\]

Here \(a\) is the damping constant and the expression is valid only for small \(a\). At line center \(\varphi_v(a,x) \sim (1+a)^{-1}\), while the core of the line is roughly \(x \sim (1+a)\) wide. The line center optical depth thus depends on \(a\) when \(a \geq 1\), while the mean optical depth is constant.

\(^1\)Note that the \text{turbulence} command accepts \(u_{\text{turb}}\) in \text{km s}^{-1} but converts it into \text{cm s}^{-1}, the units used throughout the code.
5.4.6 Mean vs. line center optical depths

**CLOUDY** works with line center optical depths throughout (see, for example, Mihalas, 1978). However, mean optical depths are reported in the final printout. For comparison, the line center optical depth is $\pi^{1/2}$ times smaller than the mean optical depth when the damping constant $a$ is small, $a \ll 1$.

In many places routines or approximations using mean optical depths are encountered (e.g., Hummer and Kunasz, 1980). The difference is in how equation 5.19 is normalized.

5.5 The Einstein coefficients

The dimensionless oscillator strength $g_f$ is related to the transition probability $A_{ul}$ [s$^{-1}$] by

$$g_l f_{l,u} = g_u f_{u,l} = \frac{m_e c \lambda_{cm}^2}{8 \pi^2 q_e^2} g_u A_{u,l} = 1.4992 g_u A_{u,l} \lambda_{cm}^2 = 1.4992 \times 10^{-8} g_u A_{u,l} \lambda_{\mu m}^2$$

(5.20)

where $\lambda_{\mu m}$ is the wavelength in microns and $\lambda_{cm}$ the wavelength in centimeters. The absorption oscillator strength is related to the transition probability by

$$f_{l,u} = \frac{m_e c \lambda_{cm}^2}{8 \pi^2 q_e^2} g_l A_{u,l} = 1.4992 \times 10^{-8} A_{u,l} \lambda_{\mu m}^2 \frac{g_u}{g_l}$$

(5.21)

or

$$A_{u,l} = \frac{8 \pi^2 q_e^2 g_l}{m c \lambda_{cm}^2 g_u} f_{abs} = \frac{f_{l,u}}{1.4992 \times 10^{-8} \lambda_{\mu m}^2 g_u} \left[ s^{-1} \right].$$

(5.22)

Combining equations 5.3 and 5.21 we obtain an expression relating the transition probability and the absorption cross section;

$$\alpha_{\nu} = \frac{\lambda^3 g_u}{8 \pi g_l \pi^{1/2} u_{Dop}} \varphi_{\nu} (x)$$

$$= \frac{\lambda^3 g_u}{8 \pi g_l \pi^{1/2} u_{Dop}} \varphi_{\nu} (x) \left[ \text{cm}^2 \right].$$

(5.23)

The coefficient for induced emission, $B_{ul}$, is related to $A_{ul}$ by the phase space factor $2h \nu^3/c^2$;

$$A_{u,l} = \frac{2h \nu^3}{c^2} B_{ul} \left[ s^{-1} \right]$$

(5.24)

and the induced emission and absorption probabilities are related by

$$g_l B_{l,u} = g_u B_{u,l}$$

(5.25)

The absorption cross section $\alpha_{\nu}$ is related to $B_{l,u}$ by

$$\alpha_{\nu} = \frac{h c}{4 \pi^{3/2} u_{Dop}} \varphi_{\nu} (x) \left[ \text{cm}^2 \right].$$

(5.26)

In these terms the optical depth increment (equation 5.1) is given by

$$d \tau_{l,u} = \alpha_{\nu} (n_l - n_u g_l/g_u) f (r) \, dr$$

$$= \frac{h c}{4 \pi^{3/2} u_{Dop}} \varphi_{\nu} (x) (n_l - n_u g_l/g_u) f (r) \, dr .$$

(5.27)
5.6 Continuum pumping

5.6.1 Photon occupation number

The intensity of a radiation field can be thought of as two parts, the available volume of phase space $2h\nu^3/c^2$ and a dimensionless occupation number $\eta$ giving the fraction of that space that is filled. Occupation numbers can be larger than unity for photons, which are Bose-Einstein particles.

For reference, the Planck function is given by

$$B_\nu = I_\nu = \frac{F_\nu}{\pi} = \frac{2h\nu^3}{c^2} \exp(h\nu/kT) - 1 \quad \text{[erg cm}^{-2} \text{ s}^{-1} \text{ sr}^{-1} \text{ Hz}^{-1}]$$

(5.28)

where $F_\nu$ is the single-hemisphere emittance from an opaque surface. The photon occupation number of a blackbody is then

$$\eta_\nu = \frac{1}{\exp(h\nu/kT) - 1} \quad (5.29)$$

The dimensionless occupation number for any continuum with a mean intensity $J_\nu$ (erg cm$^{-2}$ s$^{-1}$ Hz$^{-1}$ sr$^{-1}$) at a frequency $\nu$ is defined as

$$\eta_\nu = J_\nu/(2h\nu^3/c^2) \equiv [\exp(h\nu/kT_{ex}) - 1]^{-1}. \quad (5.30)$$

Here $T_{ex}$ is the excitation temperature of the continuum at the frequency.

5.6.2 Pumping rates

Continuum fluorescence is treated as in Ferland and Rees (1988) and Ferland (1992). The rate of induced radiative excitation by continuum photons (continuum pumping) is given by

$$r_{l,u} = n_lB_{l,u}J_{l,u} = n_lA_{u,l}J_{l,u} \frac{g_u}{g_l} = n_lA_{u,l} \eta_\nu \frac{g_u}{g_l} \quad \text{[cm}^{-3} \text{ s}^{-1}]$$

(5.31)

where $\eta_\nu$ is the dimensionless continuum occupation number at the line energy. The rate of induced radiative de-excitation is related by detailed balance and is given by

$$r_{u,l} = r_{l,u} \frac{g_l}{g_u} \quad \text{[cm}^{-3} \text{ s}^{-1}]. \quad (5.32)$$

The occupation number has the advantage that the Einstein $B$’s do not enter any rate equations. All radiative rates can be expressed in terms of an $A$ and $\nu$.

5.6.3 Optical depth effects

The line becomes self-shielding when the optical depth is greater than unity. The line optical depth between the current position and the illuminated face of the slab is used to evaluate the inward-looking escape probability, the probability that a line photon will travel this distance in a single scattering. Line optical depths do not directly affect $\eta_c$, only continuous opacities do. The final form of the continuum pumping rate is

$$r_{l,u} = n_lA_{u,l} \eta_\nu \frac{g_u}{g_l} \eta_{l,u}(\tau) \quad \text{[cm}^{-3} \text{ s}^{-1}]$$

(5.33)
5.6. CONTINUUM PUMPING

Figure 5.1: This figure shows the probability that a photon will penetrate to the line center optical depth shown on the x-axis, and then be absorbed by the line. The curves are for various values of the damping constant $a$ (the ratio of damping width to Doppler width), as indicated on the figure.

where $\gamma_{l,u}$ is the probability that continuum photons penetrate an optical depth $\tau_o$ and are then absorbed by an atom:

$$\gamma_{l,u} = \frac{\int_0^\infty \varphi_\nu \exp(-\tau_o \varphi_\nu) \, d\nu}{\int_0^\infty \varphi_\nu \, d\nu}. \quad (5.34)$$

where $\varphi_\nu$ is the Voigt function. Figure 5.1, taken from Ferland (1992), shows $\gamma_{l,u}$ for a wide variety of values of the damping constant $a$.

The code works in terms of the flux of photons per energy mesh point. The transmitted continuum has a flux of photons $\varphi_\nu$ (photons cm$^{-2}$ s$^{-1}$ Ryd$^{-1}$). The photon occupation number of the attenuated continuum is given by equation 5.29 above, here written as

$$\eta_\nu = \varphi_\nu \frac{c^2}{8\pi v_1^2 v_{Ryd}^2} \quad (5.35)$$

where $v_{Ryd}$ is the frequency in Rydbergs, $v_1$ is the frequency of 1 Rydberg, and the other symbols have their usual meaning. Continuum pumping is included among the general line excitation processes for all lines considered by the code.
5.7 Kirchhoff’s Law

Kirchhoff’s law is the statement that, in thermodynamic equilibrium, the energy emitted is equal to the energy absorbed. If the emission and absorption coefficients are $j_\nu$ and $\kappa_\nu$ then

$$ j_\nu = \kappa_\nu B_\nu(T) $$

(5.36)

where $B_\nu(T)$ is Planck’s function.

5.8 The line source function and mean intensity

The source function for a line is defined as

$$ S_l(T_{exc}) \equiv B_l(T_{exc}) \equiv \frac{A_u n_u}{B_{l,u} (n_l - n_u g_l / g_u)} [\text{erg Hz}^{-1} \text{sr}^{-1} \text{s}^{-1}]. $$

(5.37)

where $T_{exc}$ is the line excitation temperature

$$ \frac{n_u / g_u}{n_l / g_l} = \exp \left[ -\frac{h \nu}{k T_{exc}} \right] $$

(5.38)

$B_l(T_{exc})$ is the Planck function at the line excitation temperature and the line emission and absorption coefficients $j_l$ and $k_l$ enter through Kirchhoff’s law. Combining with the definitions of the Einstein relations we find the relation

$$ S_l(T_{exc}) = \frac{2h\nu^3}{c^2} \frac{n_u / g_u}{(n_l / g_l - n_u / g_u)} [\text{erg Hz}^{-1} \text{sr}^{-1} \text{s}^{-1}]. $$

(5.39)

The radiation field within the line is given by the mean intensity $\bar{J}$. $\bar{J}$ and $S_l$ are related by the net radiative bracket, which we approximate as the escape probability $P_{esc}$:

$$ P_{esc} \equiv 1 - \frac{\bar{J}}{S_l}. $$

(5.40)

The mean intensity is then give by

$$ \bar{J} = S_l (1 - P_{esc}). $$

(5.41)

and the line center photon occupation number is

$$ \eta_l = \frac{n_u / g_u}{(n_l / g_l - n_u / g_u)} (1 - P_{esc}). $$

(5.42)

5.9 Level populations in radiative equilibrium limit

For a two-level system where collisions can be neglected, in the optically thin limit, the balance equation relating the populations of a two-level system is given by

$$ \frac{dn_u}{dt} = n_l B_{lu} \bar{J} - n_u (A_{ul} + B_{ul} \bar{J}) \ [\text{cm}^{-3} \text{s}^{-1}]. $$

(5.43)
In the time-steady limit, where the time derivative is zero, the balance can be rewritten in terms of the transition probabilities as

\[ n_u (A_{ul} + A_{ul} \eta) = n_u A_{ul} (1 + \eta) = n_l A_{ul} \eta \frac{g_u}{g_l} \quad \text{[cm}^{-3} \text{s}^{-1}] \]. (5.44)

In the limit where \( \eta \) is small every photoexcitation is followed by spontaneous decay, while in the limit where \( \eta \) is large the level populations are given by the ratio of statistical weights, i.e., \( T_{exc} \) is infinite.
Chapter 6

LINE DETAILS

6.1 Overview

The effects of optical depths, continuum pumping, collisions, and destruction by background opacity, are computed for all permitted and intercombination lines. The cooling is usually distributed among many lines in high-density models, and these lines are usually optically thick. This section describes the methods and data structures used within the code to accomplish this.

6.2 Line Boltzmann factors

The Boltzmann factor $\frac{h\nu}{kT}$ for a line with a known wavelength or energy is given by Table 6.1. The table lists the ratio $\frac{h\nu}{k}$ for various units of the line energy. Vacuum, not air, wavelengths, must be used for all quantities involving wavelengths.

6.3 Air vs vacuum wavelengths

The convention across physics and astronomy is to give line wavelengths in vacuum for $\lambda \leq 2000$ Å and in air for $\lambda > 2000$ Å. There is no choice—if you observe visible light with HST the wavelengths must be quoted in air.

Air wavelengths are smaller than vacuum wavelengths because the wavefronts are crushed as then enter the denser medium with its higher index of refraction. The frequency is unchanged.

6.4 The line escape probability functions

6.4.1 Escape probability formalism vs exact radiative transfer

Radiative transport effects are approximated with the escape probability formalism (EPF). This includes line pumping by the incident continuum, photon destruction by collisional deactivation or by continuous opacities, and line overlap in special cases. This section describes how the escape probability is related to the net radiative bracket, the formally correct term in the transfer equation.

The full balance equation for radiative losses and gains for the upper level of a two level atom is given by

\[ n_u A_{ul} + n_u B_{ul} \bar{J} - n_l A_{lu} \rho_{ul} \approx n_u A_{ul} P_{ul} \quad (6.1) \]

where \( A \) and \( B \) are the Einstein coefficients, \( \bar{J} \) is the mean intensity averaged over the line, and \( \rho_{ul} \) is the net radiative bracket, defined as

\[ \rho_{ul} \equiv 1 - \bar{J}/S \quad (6.2) \]

where \( S \) is the line source function. The essence of the EPF is to replace \( \rho_{ul} \) with the escape probability \( P_{ul} \) on the argument that the difference between \( J \) and \( S \) is due to photons leaking away from the region. (Elitzur et al., 1983; Sec 2.6) shows that this is exact if \( S \) is constant across the line-forming region. In the code \( \rho_{ul} \) is replaced with \( P_{ul} \).

6.4.2 Redistribution functions

At low densities, line scattering for a two-level atom is coherent in the atom’s reference frame and the line profile function is described by the incomplete redistribution function. At high densities the Stark effect can broaden the line. When the radiation density is high, scattering within excited states can inhibit the broadening of resonance lines such as L\( \beta \) (line interlocking), destroying the coherence of the scattering process. In these cases complete redistribution in a Doppler core more closely describes the scattering process.

CLOUDY uses several escape probability functions to take these processes into account. Strong resonance lines are treated with partial redistribution with a Voigt profile. Subordinate lines are treated with complete redistribution in a Doppler core.

6.4.3 Incomplete redistribution

Incomplete redistribution is assumed for resonance transitions such as C IV \( \lambda 1549 \) and the L\( \alpha \) transitions of hydrogen and helium. Two studies of line formation using this approximation are those of Bonilha et al. (1979) and Hummer and Kunasz (1980). Both studies suggest escape probabilities of the form

\[ P_l(\tau) = \left\{ 1 + b(\tau) \tau \right\}^{-1} \quad (6.3) \]

but there is substantial disagreement in the form and value of the factor \( b(\tau) \), sometimes by more than a factor of 2. (This is after due allowance for the different definitions of line opacities in the two papers.) CLOUDY uses the Hummer and Kunasz (1980) results for H I, He I, and He II L\( \alpha \) and strong resonance lines such as C IV \( \lambda 1549 \). Their tabulated values were fitted by interpolation.
6.4. Damping constant

The damping constant $a$ is given by

$$ a = \frac{\Gamma}{4\pi \Delta
\nu_D} = \frac{\lambda_{cm} \sum A}{4\pi u_{Dop}} = \frac{\lambda_{cm} 7.958 \times 10^{-2} \sum A}{u_{Dop}} = \frac{\lambda_{\mu m} 7.958 \times 10^{-6} \sum A}{u_{Dop}} \quad (6.4) $$

where $\Gamma$ is the inverse lifetime of the level (the sum of the $A$'s from the upper level), $\Delta
\nu_D$ is the Doppler width in frequency units (Mihalas, 1978), $\lambda_{cm}$ and $\lambda_{\mu m}$ are the wavelengths in cm and microns respectively, and $u_{Dop}$ is the Doppler width in cm s$^{-1}$. The ratio $\Gamma \lambda / 4\pi$ is stored in the line structures and the $a$'s are evaluated using this ratio and the current Doppler width.

6.4.5 Background opacity and Destruction probability

The ratio of continuous to total opacity is $X_c$ parameterized as

$$ X_c = \frac{\sum \kappa_c n_c}{\kappa_l n_l + \sum \kappa_c n_c} \quad (6.5) $$

where the $\kappa_l$'s are the line center absorption opacities and the $n$'s the number of absorbers.

6.4.6 Complete redistribution

Lines arising from excited states (hydrogen Balmer, Paschen, etc.) and Lyman lines with $n_u > 2$ are treated assuming complete redistribution in a Doppler core (i.e., the damping constant $a$ is assumed to be zero). This assumption can be changed with the atom redistribution command. If the total optical depth of the slab is $T$, then the escape probability at a depth $\tau$ from the illuminated face is given by;

$$ P_{u,l}(\tau, T, X_c) = \left[ 1 - X_c F(X_c) \right] \frac{1}{2} \left[ K_2(\tau, X_c) + K_2(T - \tau, X_c) \right] \quad , \quad (6.6) $$

and the destruction probability is

$$ D_{u,l}(X_c) = X_c F(X_c) \quad . \quad (6.7) $$

The function is

$$ F(X_c) = \int_{-\infty}^{\infty} \frac{\varphi(x)}{X_c + \varphi(x)} \, dx \quad , \quad (6.8) $$

where in these expressions (and in this part of the code) the mean opacity is used, and $\varphi(x) \approx \pi^{1/2} \exp(-x^2)$ is the Voigt function. $F(X_c)$ is interpolated from the tables presented by Hummer (1968). The function

$$ K_2(\tau, X_c) \equiv \frac{1}{1 - X_c F(X_c)} \int_{-\infty}^{\infty} \frac{\varphi^2(x)}{X_c + \varphi(x)} E_2 \left[ (X_c + \varphi(x)) \tau \right] d\tau \quad (6.9) $$

is evaluated numerically.

The complete redistribution escape probabilities are corrected for finite damping parameters by including a separate wing escape probability. The resulting total escape probabilities have been
tested against numerical integrations of the exact formulae in Avrett and Loeser (1966); Hummer and Rybicki (1982) – note the different definitions of $K_2$ in these papers – verified by comparison by the tabulations and fits in these papers. The overall fit to the escape probability is in error by at most 25% in the range $a = 10^{-3} - 10^{3}$, with the largest error at $\tau \simeq 1$, and correct asymptotic behaviour in the low $\tau$ and high $\tau$ limits. This level of accuracy is thought to be sufficient, given the other approximations inherent in the escape probability method.

### 6.4.7 Masing lines

A line mases when its optical depth is negative. The escape probability is (Elitzur, 1992; p 32)

$$P_{u,l} = 1 - \exp\left(-\frac{\tau}{\tau}\right).$$

(6.10)

The code will generate a comment if strong maser action occurs for any transition.

### 6.4.8 Stark broadening

Distant collisions with charged particles broaden the upper levels of lines, and in the limit of very high densities this will make the scattering process completely non-coherent even for $L\alpha$ (i.e., complete redistribution obtains). Cloudy closely follows the treatment of Puette (1981) in treating Stark broadening.

### 6.4.9 Net escape probability

A total escape probability $P_{l,tot}$, given by

$$P_{u,l} = \min(P_{inc} + P_{Stark}, P_{com}),$$

(6.11)

is defined for transitions described by incomplete redistribution. The escape probabilities are those for incomplete, Stark, and complete redistribution respectively. The total effective escape probability is not allowed to exceed the complete redistribution value for $\tau > a^{-1}$.

If $\tau$ is the optical depth in the direction towards the source of ionizing radiation and $T$ is the total optical depth computed in a previous iteration, then the escape probability entering the balance equations is

$$P_{u,l}(\tau, T) = \frac{\{P_{u,l}(\tau) + P_{u,l}(T - \tau)\}}{2}.$$

(6.12)

In general the total optical depth $T$ is only known after the first iteration, so more than one iteration must be performed when radiative transfer is important.

### 6.5 Optical depths and the geometry

The terms open and closed geometry are defined in a section in Part I. The treatment of transfer in these two limits is described here.
6.6. COLLISION STRENGTHS

6.5.1 Open geometry

This is the default. During the first iteration the line optical depth is defined using only optical depths accumulated in the inward direction. This optical depth is initialized to a very small number at the start of the calculation. At the end of the first iteration the total optical depth is set to the optical depth accumulated in the inward direction. At the end of subsequent iterations the total optical depth is defined as a mean of the new and old inward optical depths.

6.5.2 Closed geometry overview

Continuum photons are assumed to interact with gas fully covering the continuum source. At the end of the first iteration the total continuum optical depths are set equal to twice the computed optical depths, and the inner optical depths reset to the computed optical depths. The same recipe is followed on subsequent iterations, except that means of old and newly computed optical depths are used.

Closed expanding geometry This is the default if the sphere command is entered. In this case it is assumed that line photons do not interact with lines on the “other” side of the expanding spherical nebula. The treatment of line optical depths is entirely analogous to that described for an open geometry, since the presence of the distant material has no effect on line transfer.

Closed static geometry This is assumed if the sphere static command is entered. In this case line photons from all parts of the spherical shell do interact. As a result the optical depth scale is poorly defined on the first iteration, and more than one iteration is required. On second and later iterations the total line optical depth is set to twice the optical depth of the computed structure, and the optical depth at the illuminated face of the shell is set to half of this. The optical depth scale is only reliably defined after at least a second iteration.

6.5.3 Wind

The model is a large velocity gradient \( v \propto R \) Sobolev approximation) wind. This is described further in Part 2 of this document.

6.6 Collision strengths

I have tried to follow the Opacity Project notation throughout this document (Lanzafame et al., 1993). The energy-specific collision strength \( \Omega_{lu} \) for a transition between upper and lower levels \( u \) and \( l \) is related to the excitation cross section \( Q_{lu} \) by

\[
Q_{lu} = \frac{\pi \Omega_{lu}}{g l k_{lu}^2} \quad [\text{cm}^2]
\]

(6.13)

where \( k_{lu}^2 \) is the wavenumber of the collision energy. If the collisions are with thermal electrons having a Maxwellian velocity distribution \( f(u) \) and velocity \( u \) then the rate coefficient \( q_{lu} \) is given by

\[
q_{lu} = \int_0^\infty f(u)uQ_{lu}du = \frac{2\pi^{1/2}h^2}{g l m_e} a_o \left( \frac{R_{\infty}}{kT} \right) \gamma_{lu} \exp \left( -\frac{E_{lu}}{kT} \right) \sqrt{\frac{2kT}{m_e}} \quad [\text{cm}^3\text{s}^{-1}].
\]

(6.14)
$E_{ul}$ is the transition energy in Rydbergs, $a_o$ is the Bohr radius,
\[
a_o = \frac{\hbar^2}{m_e q_e^2} = 0.529177249 \times 10^{-8} \text{ cm} \quad (6.15)
\]
and $R_\infty$ is the Rydberg energy. Then the thermally-averaged collision strength is given by
\[
\Upsilon_{lu} = \int_0^\infty \Omega_{lu} \exp \left( -\frac{\varepsilon}{kT} \right) d\left( \frac{\varepsilon}{kT} \right). \quad (6.16)
\]
The rate coefficient for collisional de-excitation is then given by
\[
q_{ul} = \Upsilon_{lu} \frac{g_u}{g_l} \exp (-\chi) = \frac{\Upsilon_{lu} \times 10^{-6}}{g_l \sqrt{T_e}} \exp (-\chi) \, [\text{cm}^3\text{s}^{-1}]. \quad (6.17)
\]
The rate coefficient for excitation follows from detailed balance:
\[
q_{lu} = q_{ul} \frac{g_u}{g_l} \exp (-\chi) = \frac{\Upsilon_{lu} \times 10^{-6}}{g_l \sqrt{T_e}} \exp (-\chi) \, [\text{cm}^3\text{s}^{-1}]. \quad (6.18)
\]

### 6.7 Born approximation

The Born approximation is valid for energies much larger than the excitation energy of the transition. The energy specific collision strength is given by Bethe (1930) as
\[
\Omega_{lu} \approx \frac{4g_l f_{lu}}{E_{lu}} \ln \left( \frac{4\varepsilon}{E_{lu}} \right) \quad (6.19)
\]
where $f_{lu}$ is the absorption oscillator strength of the permitted transition.

### 6.8 The g-bar approximation

The g-bar or van Regemorter (1962) approximation relates the collision strength to the transition probability $A_{ul}$ and wavelength $\lambda$ (in $\mu$m). Here, the collision strength for the downward transition $\Upsilon_{ul}$ is approximately given by
\[
\Upsilon_{ul} \approx \frac{2\pi m_e^2 \lambda^3 \mu_{ul} 10^{-12} g_u A_{ul} \bar{g}}{\sqrt{3} \hbar^3} \approx 2.388 \times 10^{-6} \lambda^3 \mu_{ul} g_u A_{ul} \bar{g} \quad (6.20)
\]
where $g_u$ and $g_l$ are the statistical weights of the upper and lower levels and $f_{abs}$ is the absorption oscillator strength. For energies of interest in astrophysical plasmas, where $kT < h\nu$, $\bar{g}$ is approximately given by
\[
\bar{g} \approx \begin{cases} 
0.2; & \text{positive ions} \\
(kT/h\nu) / 10; & \text{neutrals}
\end{cases} \quad (6.21)
\]
(van Regemorter 1962). These approximations are generally accurate to better than 1 dex. Gaetz and Salpeter (1983) give improved forms of the approximation.
6.9 The critical density

The critical density is defined as the density at which the radiative de-excitation rate $A_{ul}P_{ul}$ (where $A$ is the transition probability and $P$ is the escape probability) equals the collisional de-excitation rate $q_{ul}n_e$. Setting

$$A_{ul}P_{ul} = C_{ul} = q_{ul}n_e = \Upsilon \frac{8.629 \times 10^{-6}}{g_u \sqrt{T_e}} n_e \text{ [s}^{-1}]$$

where $\Upsilon$ is the thermally averaged collision strength, the critical density is given by

$$n_{\text{crit}} \sim \frac{A_{ul}P_{ul}g_u\sqrt{T_e}}{\Upsilon 8.629 \times 10^{-6}} \text{ [cm}^{-3}]$$

(6.23)

For an optically allowed transition, in which the g-bar approximation may apply, this density is approximately given by

$$n_{\text{crit}} = \frac{4.8 \times 10^{10} \sqrt{T_e}}{\lambda_{jms}^3} \text{ [cm}^{-3}]$$

(6.24)

6.10 Line thermalization length

Line radiative transfer will affect the thermal equilibrium of the gas when the collision time scale approaches an effective lifetime $\tau \sim A_{ul}/n_{\text{scat}}$, where $A_{ul}$ is the transition probability and $n_{\text{scat}}$ is the number of scatterings a line photon undergoes before escape. For permitted metal lines (which often have optical depths $\sim 10^4 - 10^6$) line thermalization becomes important at densities $n_e > 10^{15}/\tau 10^{10} \text{cm}^{-3}$. These effects are important for hydrogen at considerably lower densities due to its greater abundance. Additionally, continuum transfer affects the ionization and thermal equilibrium of the gas at all densities.

6.11 Averaging levels into terms

6.11.1 Collision strengths

Often cases are encountered in which a multiplet consisting of many lines can be treated as the equivalent two-level atom with a single transition. In these cases it is necessary to define “effective” collision strengths and transition probabilities. If the collision strength from an individual level $i$ is $\Upsilon_i$, and the statistical weights of the level and term are $g_i$ and $g_{\text{tot}}$ respectively, then the effective collision strength $\Upsilon_{\text{eff}}$ is related to $\Upsilon_i$ by a simple argument. The collision rate $q_i$ is proportional to the ratio

$$n_i q_i \propto n_i \frac{\Upsilon_i}{g_i} \text{ [s}^{-1}]$$

(6.25)

so that

$$n_{\text{tot}} q_{\text{tot}} = \sum_i n_i q_i \propto \sum_i n_i \frac{\Upsilon_i}{g_i} \text{ [s}^{-1}]$$

(6.26)
In many cases it is valid to assume that the levels within the term are populated according to their statistical weight, viz.,

\[ n_i = n_{tot} \frac{g_i}{g_{tot}} \text{ [cm}^{-3}] \] .

(6.27)

Then, the effective collision strength \( \Upsilon_{tot} \) is operationally defined by the relations

\[ n_{tot} \frac{\Upsilon_{tot}}{g_{tot}} = \sum_i n_i \frac{\Upsilon_i}{g_i} = n_{tot} \frac{\sum_i \Upsilon_i}{g_{tot}} . \]

(6.28)

So, the effective collision strength of the entire multiplet is

\[ \Upsilon_{tot} = \sum_i \Upsilon_i . \]

(6.29)

### 6.11.2 Transition probabilities

Under similar circumstances an effective transition probability \( A_{eff} \) may be defined as

\[ n_{tot} A_{tot} = \sum_i n_i A_i = n_{tot} \sum_i \frac{g_i}{g_{tot}} A_i \]

so that the effective transition probability is

\[ A_{tot} = \sum_i \frac{g_i}{g_{tot}} A_i . \]

(6.30)

(6.31)

So collision strengths are added, and transition probabilities averaged.

### 6.12 Level populations with collisions

Both escape and destruction probabilities enter in the calculation of a level population and line emissivity. The escape probability \( P_{u,l} \) is the probability that a line photon will escape in a single scattering (Elitzur et al., 1983; Elitzur, 1984). The destruction probability \( D_{u,l} \) is the probability that a line photon will be destroyed in a single scattering.

The line de-excitation rate is given by

\[ \left( \frac{dn_u}{dt} \right)_{rad} = n_u A_{u,l} (P_{u,l} + D_{u,l}) - n_l A_{u,l} \eta \gamma_{u,l} + n_u C_{ul} - n_l C_{lu} \text{ [cm}^{-3}\text{s}^{-1}] \]

(6.32)

where \( \eta \) is the photon occupation number of the attenuated external radiation field, \( C \) is the collision rate (s\(^{-1}\)), and \( \gamma_{u,l} \) is the fluorescence probability.

The net emission from a transition between the level \( n \) to a lower level \( l \) and escaping to the surface is then

\[ 4\pi j(n,l) = n_n A_{n,l} h\nu_{n,l} P_{u,l}(\tau_{n,l}) f(r) \text{ [erg cm}^{-3}\text{s}^{-1}] \]

(6.33)

where \( f(r) \) is the filling factor. The total emission from the gas is then

\[ e(n,l) = \int_V n_n A_{n,l} h\nu_{n,l} P_{u,l}(\tau_{n,l}) f(r) dV \text{ [erg cm}^{-2}\text{s}^{-1} or ergs}^{-1} \]

(6.34)
6.12. LEVEL POPULATIONS WITH COLLISIONS

depending on whether the intensity or luminosity case is chosen. The local cooling rate (erg cm\(^{-3}\) s\(^{-1}\)) due to the line is related to the level populations by

\[
\Lambda_{u,l} = (n_l C_{l,u} - n_u C_{u,l}) \int (r) h \nu \quad [\text{erg cm}^{-3}\text{s}^{-1}]
\]

(6.35)

and the local flux (cm\(^{-2}\) s\(^{-1}\)) of “on-the-spot” (OTS) photons caused by line loss (used to compute heating or photoionization rates for the sources of the background opacity) is

\[
\phi_{OTS} = \frac{n_u A_{u,l} D_{u,l}(X_c)}{\sum \kappa_c n(c)}.
\]

(6.36)

The ratio of inward to total line intensity is then given by

\[
\frac{4\pi j(in)}{4\pi j(total)} = \frac{P_{u,l}(\tau)}{[P_{u,l}(\tau) + P_{u,l}(T - \tau)]}.
\]

(6.37)
Chapter 7

CLOUDY AS A STANDALONE PROGRAM

CLOUDY can be used to run a single model, to create large grids of calculations, or to compute a number of simulations while varying one or more parameters to match an observed spectrum. This Chapter describes how to use CLOUDY as a self-contained program to read in the parameters for the simulation and compute the result. The next Chapter discusses the case in which the code is called as a subroutine of another larger code.

7.1 Running a single model with a shell script

The code reads from an input file and can create a large number of output files. The latter include both the main output (described in Chapter 1, OUTPUT) and the ancillary “save” files (described in the Chapter 15 of Hazy 1, CONTROLLING OUTPUT).

It is a good idea to follow a naming convention for these files. The convention I use is the style “basename.type” where basename explains the astrophysical context (for instance, “quasar” or “IGM”) and type gives the type of information in the file. For instance, a model of a planetary nebula may have the base name “pn_halo”, the input script might be pn_halo.in, the output would be in pn_halo.out, and the file created by the save overview command might be pn_halo.ovr. Then all of these files could be located with a simple “ls pn.*” and all overview files with a “ls *.ovr” on a Linux system.

The pn.in file contains the input commands that tell the program what to do. A typical example might be the following:

```plaintext
// log of the hydrogen density (cm^-3) 
hd 4
// log of the inner radius (cm) 
radius 17
// black body temperature and total luminosity
black body 1e5 K, luminosity 38
save overview "pn.ovr"
```

CLOUDY stops reading the input stream when it reaches either an empty line or the end of file. Nothing special is needed at the end of the input file.
I have a shell script named `run` which is in my “bin” directory, which I include on my path. The shell script `run` consists of the following on Linux:

```bash
cloudy.exe < $1.in > $1.out
```

Under Windows it would have the name `run.bat` and would contain the following

```bash
cloudy.exe < %1.in > %1.out
```

If `run` is executed by typing

```bash
run pn
```

it would read the input stream in `pn.in` and create an output file called `pn.out`.

### 7.2 Running a single model from the command line

The code also has two command-line options that will accomplish the same thing as the shell script described in the previous section. If you create an executable called `cloudy.exe`, then the command

```bash
cloudy.exe model.in
```

will read input from `model.in`, write output to `model.out`, and add the prefix `model` to all the save files. This can also be written

```bash
cloudy.exe -p model
```

Alternatively, you can use the command

```bash
cloudy.exe -r model
```

which does the same thing, except that it will not add the prefix `model` to all the save files (mnemonic: `-p` will Prefix Save file names, while `-r` will only Redirect input and output).

By typing the command

```bash
cloudy.exe -h
```

you can a list of all the command line flags that `CLOUDY` supports. There are two additional flags, `-a` and `-g`, that are used for debugging the code and internally in grid runs. They should never be used in normal situations.

### 7.3 Running grids of simulations or optimizing a simulation

The greatest insight is gained by creating grids of simulations which vary one or more of the input parameters to show how various predictions change, or to optimize the agreement between the predicted and observed values. One example, the predicted C IV `lambda`1549 equivalent width as a function of the flux of ionizing photons and cloud density, is shown in Figure 8.1. See Baldwin et al. (1995c) for more details.

Such grids of simulations can be made parallel on distributed memory parallel machines because each point in the grid is independent of the other points.
7.4 Parallel processing with MPI

Peter van Hoof created a wrapper for the grid and optimize commands. CLOUDY will automatically run these commands using all available processors if the code is compiled with an MPI aware compiler and run on an appropriate computer.
Chapter 8

CLOUDY AS A SUBROUTINE

8.1 Overview

CLOUDY is designed to be used as a subroutine of other, much larger, codes. When used this way a series of subroutine calls, described next, are used to initialize the code, specify the initial conditions, do the simulation, and finally examine the predictions.

A common strategy is to call the code to compute line intensities for a large matrix of parameters. The results of one such calculation is shown in Figure 8.1 (Baldwin et al., 1995b; Ferland, 2003). Such grids can be computed in a few dozen hours on modern workstations, and offer far greater insight to physical effects of changing model parameters than does a single model.

Much of this can be done without writing a program, by using the grid command. This command was introduced by Ryan Porter in C07.02, and makes it possible to create large grids of models like those shown in Figure 8.1 with commands. The grid command is described in Part 1 of this document. There are several save output commands that are designed to save information from grid calculations.

8.1.1 Host languages

CLOUDY is written in C++, and it assumed for most of this section that CLOUDY will be called from an external C or C++ program.

However, there is experimental support for a number of other languages.

You can call a C++ program like CLOUDY from a Fortran program by using the cfortran.h header file described at http://www-zeus.desy.de/~burow/cfortran/. I have never tried this. Good luck.

In the subdirectory sys_gcc_shared, an additional set of Makefile targets are set up to use the subroutine API described below for Perl and Python scripts, using the SWIG interface generator. In this directory, there is also an experimental direct interface to the Lua scripting language.
Figure 8.1: The results of a large grid of quasar emission-line cloud calculations are shown. The $x$-$y$ plane shows the logs of the hydrogen density ($\text{cm}^3$) and flux of ionizing photons ($\text{cm}^{-2} \text{s}^{-1}$). The $z$ axis is the predicted line equivalent width.
8.1.2 Creating a new main program

In C++ there must be exactly one main program and it must be called main. This routine is within the file maincl.cpp in the source downloaded from the web. You need to replace the existing CLOUDY main program with one that you write. The file maincl.cpp that is included in the distribution must be deleted so that the program you write will be loaded instead. The remaining routines are then compiled with a command like the following:

```
g++ -O3 -c *.cpp
```

which will create a large number of object files. The new main program will then need to be linked with these object files with a command something like

```
g++ -O3 -o mycloudy.exe newmain.cpp *.o -lm
```

Alternatively, if you are using the Makefile build process and have already built CLOUDY, you can use the library file libcloudy.a which contains all the object files with the command

```
g++ -O3 -o mycloudy.exe newmain.cpp -L. -lcloudy -lm
```

The following subsections outline how to write code for this new main program.

8.1.3 The cddefines.h and cddrive.h header files

The file cddrive.h contains definitions of all public routines, the routines that a user would call to drive CLOUDY. That file is the definitive reference for the material contained in this section and is more up to date than this document. Comments within that file explain all routines and their parameters.

The header cddefines.h should come before cddrive.h since it includes many definitions and includes the standard C++ header files that are needed to drive the code. The first two header files in the new main routine should be the following:

```
#include "cddefines.h"
#include "cddrive.h"
```

8.1.4 The template for main programs

C++ exceptions are used by CLOUDY. The main program must catch these exceptions. If it does not then the code will crash with an unhandled exception and output files will not be complete. This requires that the main program start with a C++ “try” block and that exception handlers be included within the main program. The adventurous user may enjoy creating their own try block/exception handlers.

A sample template, in the file template.cpp, includes the needed code and can be used to create your own programs. It is included in the programs directory below the tsuite directory in the program download. That version includes a simple call to run the code’s smoke test. You would replace the existing code with your own.
8.1.5 A note on return conditions

Some of the routines return a value to indicate success or failure. I try to follow the C and Unix conventions to indicate success with zero (or false) and trouble with a non-zero return (or true). This rule is not always followed (it is not followed by the important routine cdLine), however, and cddrive.h should be consulted to make sure the return conditions are understood.

8.2 Initializing the code

Many variables must be initialized at the beginning of the calculation. Calling routine cdInit does this.

    cdInit();

Routine cdInit must be called every time a new calculation is to be performed, before calling any of the following subroutines, but after the results of any previous calculations have been read. (The results of any previous calculations are lost when cdInit is called.)

8.3 Handling input and output

8.3.1 cdTalk—produce output?

CLOUDY normally speaks what’s on its mind. This would generate too much output in a large grid. It does have a quiet mode in which nothing at all is printed. This quiet mode is set by the logical argument to subroutine cdTalk.

    #include "cddefines.h"
    #include "cddrive.h"
    cdInit();
    /*set no output at all*/
    cdTalk( false )
    /*have the code produce the normal printout*/
    cdTalk( true )

    The default is for CLOUDY to produce output. cdTalk does not have to be called if this is what you want. It needs to be called with the logical variable false if the quiet mode is desired.

8.3.2 cdOutput—sending output to a file

CLOUDY normally writes its standard output on the system’s stdout. This can be changed to another file by calling the routine cdOutput, which has two arguments. The first is the name of the file, and the second the mode with which the file should be opened (this is identical to the second parameter of the fopen() routine). Both parameters have default values. The default mode for opening the file is “w”, while the default filename is the empty string. Supplying an empty string as the file name means that the output will be directed back to stdout again. The output file will be automatically closed on exit of the program. If you call cdOutput multiple times with different file names, the file from the previous call will also be closed automatically.
# include "cddefines.h"
# include "cddrive.h"

/* open the file output.txt for writing with mode "w" */
/* this will overwrite an existing file */
ccdOutput("output.txt");

/* if you want to append to a file, use this instead */
ccdOutput("output.txt","a");

/* this will close output.txt and open output2.txt with mode "w" */
ccdOutput("output2.txt");

/* if you now want to redirect to stdout again, use this */
/* this will close output2.txt */
ccdOutput();

### 8.3.3 cdInput—reading input from a file

CLOUDY normally reads input from the system’s stdin. This can be changed to another file by calling the routine cdInput, which works the same way as the cdOutput command described above with the following two exceptions: the default open mode is “r”, and supplying an empty string as the file name redirects input back to stdin.

### 8.3.4 cdRead—entering Commands

Command lines are entered by successive calls to routine cdRead. The argument of cdRead is a null-terminated string containing valid commands. These commands must obey all the rules outlined in Part I.

In the examples below some commands are directly entered as strings (this works when the string is a constant) while other strings are created by writing variables through sprintf (a standard C io function). This is necessary when the value of a variable needs to be placed into a string.

```c
char chLine[200]; /* this string will hold the command lines we will generate */

/* this example sends the string straight to cdRead */
nleft = cdRead("title a series of constant pressure models");

/* write variable to a string then sends the string to cdRead */
hden = 5.4;
sprintf(chLine, "hden %5.2f ", hden);
nleft = cdRead(chLine);

/* this example sends a string that contains double quotes, * and so must "escape" them with doubled backslashes */
nleft = cdRead("save overview \"test.ovr\" ");

sprintf(chLine, "coronal %5.2f ", temp);
nleft = cdRead(chLine);

nleft = cdRead("stop zone 1 ");
```
CHAPTER 8. CLOUDY AS A SUBROUTINE

`cdRead` returns the number of commands that can still be entered before exceeding the size of the storage arrays. The return value was ignored in the examples above. So this routine is an exception to the general rule that a zero return condition indicates success—here it indicates a problem—no further commands can be entered.

It is not now possible to read in more than 4000 command lines because of limits to the size of the character arrays used to store them. This limit is stored as the variable `NKRD`. If more than 4000 lines are read in by calling `cdRead` then `cdRead` will stop after explaining why. It will be necessary to increase `NKRD` if more than 4000 command lines are needed.

### 8.4 Executing the code

#### 8.4.1 cdDrive—calling the Code

The calculation is performed when routine `cdDrive` is called. `cdDrive` returns a bool indicating whether the calculation aborted. The value `false` indicates a successful calculation. The following shows an example of its use.

```c
if( cdDrive() )
{
    printf("problems!\n");
    cdEXIT(EXIT_FAILURE);
}
```

If problems occurred and the results cannot be trusted then the return value is `true`. This will only be set if the calculation suffered a complete meltdown. Routine `cdNwcn` can be called to find out about any problems.

#### 8.4.2 cdNoExec—checking without Computing

If routine `cdNoExec` is called after `cdInit` but before `cdDrive` then only the initial parts of a calculation will be performed when routine `cdDrive` is called.

```c
cdInit();
/*read in commands */
cdRead( . . .);
/*tell it not to execute */
cdNoExec();
/*call the code */
if( cdDrive() )
    cdEXIT(EXIT_FAILURE);
```

When `cdDrive` is called after `cdNoExec` the code will generate the incident continuum, set the initial density, and derive the chemical composition. It will then stop just before the initial search for the physical conditions in the first zone. All of the initial printout, summarizing properties of the composition and continuum, will be generated. This provides a quick way to check that a large grid of models will be specified correctly without actually fully computing the grid.

8.5 Ending the code

The code must end by calling \textit{cdEXIT}. This routine will close any open output files and do other needed jobs before exiting. The full output may not be produced if this routine is not called. Routine \textit{cdEXIT} takes a single parameter, \textit{EXIT_SUCCESS} or \textit{EXIT_FAILURE}, standard macros that indicate how the program ended.

The routine \textit{cdEXIT} is a pair with \textit{DEBUG_ENTRY}. Any routine that calls \textit{cdEXIT} must also have a call to \textit{DEBUG_ENTRY} statement at the start. The routine \textit{DEBUG_ENTRY} has a single parameter, a string giving the name of the routine (which should be “main()”) in the case of the main program.

8.6 Checking Predictions

This section describes a series of routines that allow predicted quantities to be obtained after the calculation is complete.

8.6.1 \textit{cdB21cm}—mean magnetic field

The return value is the mean magnetic field weighted by $n(H^0)dr/T_{spin}$. This is related to the field measured with 21 cm Zeeman observations. A tangled magnetic field is assumed. A magnetic field is not included by default but can be added with the \textbf{magnetic field} command, described in Part 1 of this document.

8.6.2 \textit{cdColm}—the computed column densities

The predicted column densities of some species can be obtained by calling routine \textit{cdColm}:

```c
/* want N(C+2) */
if(cdColm("carb", 3 , &colum))
{
    printf(" could not find C+2\n");
}
else
{
    printf("The predicted C+2 column density is %e\n", column );
}
```

The routine returns zero if it found the species, and 1 if it could not. It returns the predicted column density [$\text{cm}^{-2}$] as the third argument. The first argument \textit{chLabel} is a four-character string that must agree with the first four characters (upper or lower case) of the name used to indicate the element in the printout. The second (integer) variable \textit{ion} is the spectroscopic designation of the level of ionization, i.e., 1 indicates the atom $C^0$, 3 indicates $C^+2$, etc.

The ion stage of 0 indicates a special case, a molecule or an excited level of an atom or ion. The label determines the species in this case. Table 8.1 gives the levels and molecules that are recognized. Many of the molecules have fewer than four characters. The label must still contain four characters and spaces are used to fill out the four.

</table>
A large and complex model of the H₂ molecule is computed when the `atom H2` command is included. It is possible to obtain column densities in any \( v, J \) level of H₂ by calling routine `cdH2_colden`.

### 8.6.3 cdCooling_last—last zone’s cooling

The return value is the total cooling rate (erg cm\(^{-3}\) s\(^{-1}\)) for the last computed zone.

### 8.6.4 cdDepth_depth—the depth structure of the cloud

This routine returns a vector giving the zone depths (in cm) of the previous iteration. The code uses adaptive logic to control the radial zoning of the model. Neither the number of depth points nor their structure is known in advance. This routine is called with a double precision vector with enough space to hold the structure. The number of depth points is determined by calling `cdnZone` and space must be allocated by the calling routine. Each element of the vector is the depth from the illuminated face to the center of zone \( n \).

### 8.6.5 cdEDEN_last—electron density of last zone

This returns the electron density (cm\(^{-3}\)) of the last zone.

### 8.6.6 cdEmis—emissivity of lines

`cdEmis` has the same arguments as `cdLine` but returns the local emissivity (erg cm\(^{-3}\) s\(^{-1}\) for unit filling factor) of the line for the last computed zone. The return value is the index of the line within the line stack if it was found, and the negative of the number of lines in the stack if the line could not be found.

### 8.6.7 cdGetLineList—sets of emission lines

The routine `cdGetLineList` provides a way to automatically access a list of emission lines.

First enter a list of emission lines into a file. One emission line occurs on each line of the file. It starts with a line label like “H 1” followed by the wavelength of the line. A set of such files is included in the data directory of the distribution files. They have names `LineList*.dat`. You can use these as examples to create your own files.

The first argument to routine `cdGetLineList` is the name of the file containing the line list. If a null string is passed (“”) then `LineList_BLR.dat` is used. The code will first try to open the file in the current directory, and if it is not present, will try on the path.

`cdInit` must be called before `cdGetLineList` is called. Next `cdGetLineList` is called, and finally, the actual grid of calculations begins. The predicted intensities of a set of lines are then extracted by calling `cdLine`.

The second and third parameters are a pair of vectors that are defined by the calling program. When the routine `cdGetLineList` is called it uses these vectors to store the labels and wavelengths. Space for the lines is allocated by `cdGetLineList` after it determines how many lines are in the file.
These string and float vectors will then contain the label and wavelength used to identify the lines. The function returns the number of lines in the list. If problems occurred then \(-1\) is returned.

The following shows an example of getting the lines from `LineList_NLR.dat`, executing the code, and then obtaining the predicted intensities of all lines listed in `LineList_NLR.dat` by calling `cdLine`.

```c
/* define variables */
exit_type exit_status = EXIT_SUCCESS;
vector<char*> chLabel;
vector<float> wl;
/* initialize the code */
cdInit();
/* get list of lines from a line list included in the distribution */
if( (nLines=cdGetLineList("LineList_NLR.dat",chLabel,wl)) < 0 )
{
    /* this is the error exit - could not obtain the lines */
    cdEXIT(EXIT_FAILURE);
}
/* missing code */
/* now do the calculation */
cdInit();
/* missing commands here, then call the code */
/* missing code */
if( cdDrive() )
    exit_status = EXIT_FAILURE;
/* now print the predicted emission line intensities */
for( long n=0; n < nLines; ++n )
{
    if( cdLine( chLabel[n], wl[n], &relative, &absolute ) < 0 )
    {
        fprintf(stderr,"did not find %s%5li\n",chLabel[n],wl[n]);
    }
    print("%.3e\n", relative);
}
/* free the memory that was allocated in cdGetLineList */
for( size_t i=0; i < chLabel.size(); ++i )
delete[] chLabel[i];
chLabel.clear();
cdEXIT(exit_status);
```

### 8.6.8 cdH2\_colden—state-specific column densities of H\(_2\)

This returns the column density of any level in the X ground electronic state of H\(_2\). This command only works when the large H\(_2\) molecule is included with the `atom H2` command. It has two integer arguments, the vibration and rotation quantum numbers of a level in X. If both are zero or greater the routine returns the column density in that level. If the vibration quantum number is negative then a summed column density is turned. If \(\nu < 0\) and \(J = 0\) it returns the total H\(_2\) column density, if \(J = 1\) it returns the ortho column density, and if \(J = 2\) the para column density. If the indices do not make sense the routine prints a message and returns \(-1\).

Here are some examples:
8.6. CHECKING PREDICTIONS

/* total H2 column density */
total = cdH2_colden(-1, 0);
/* ortho column density */
ortho = cdH2_colden(-1, 1);
/* para column density */
para = cdH2_colden(-1, 2);
/* column density in 0, 0 */
total00 = cdH2_colden(0, 0);

8.6.9 cdH2_line—an H2 emission line intensity

More than half a million H2 lines are predicted and there will be instances where two H2 lines have nearly the same wavelength. Identification of a particular transition within the list of lines can be ambiguous. This command finds the intensity and luminosity of a transition by specifying its upper and lower n, v, J levels. The first six arguments give the n, v, J indices of the upper and lower levels in that order. The last two variables are double pointers that return the intensity and luminosity of the transition. The function returns 1 if it finds the line and 0 if it did not. (This behavior follows that of cdLine rather than the standard C++ conventions on function return values.) Currently this only works for the ground electronic state.

Here is an example:

double xInten , xLumin;
/* the 1-0 S(1) at 2.121 microns */
if( cdH2_Lines( 0,1,3 , 0,0,1 , &xInten , &xLumin ) == 0 )
{
    printf("could not find line.\n");
}

8.6.10 cdHeating_last—last zone’s heating

The total heating rate (erg cm\(^{-3}\) s\(^{-1}\)) for the last computed zone is returned.

8.6.11 cdIonFrac—the computed ionization fractions

The predicted ionization fractions,\(^1\) averaged over radius, area, or volume, can be accessed by calling the subroutine cdIonFrac. The average over radius is defined as

\[
\left\langle \frac{n(S^n)}{n(S_{gas})} \right\rangle = \frac{\int n(S^n) f(l) dl}{\int n(S_{gas}) f(l) dl}
\]

where \(n(S_{gas})\) is the total gas phase density of the element. The average over area is defined as

\[
\left\langle \frac{n(S^n)}{n(S_{gas})} \right\rangle = \frac{\int n(S^n) f(r) r dr}{\int n(S_{gas}) f(r) r dr}
\]

---

\(^1\)Before version 96 the ionization fractions only included atoms and ions. They now also include molecules. The sum of the atomic and ionic fractions will not add up to unity if a significant fraction of the element is in molecules.
The average over volume is defined as

\[
\frac{\langle n(S^{+n}) \rangle}{n(S_{\text{gas}})} = \frac{\int n(S^{+n}) f(r) r^2 \, dr}{\int n(S_{\text{gas}}) f(r) r^2 \, dr}.
\] (8.3)

Two sample calls to the routine follow:

```c
/* false below means to not include electrons in the mean */
if( cdIonFrac("carb", 2, &frac, "radius", false) )
{
    cdEXIT(EXIT_FAILURE);
}
printf("The predicted ionization fraction over radius is %g\n", frac);
/* true below means to include electrons in the mean */
if( cdIonFrac("carb", 2, &frac, "radius", true) )
{
    cdEXIT(EXIT_FAILURE);
}
printf("Ionization fraction wrt radius end elec den is %g\n", frac);
```

The first argument is a four-character identifier that must agree with the first four characters (upper or lower case) used to indicate the element in the printout. The second integer argument is the spectroscopic designation of the level of ionization, i.e., 1 indicates C\(^0\), 3 indicates the second ion C\(^+2\), etc. The third argument returns the predicted ionization fraction \(S^{+n}/S_{\text{gas}}\). The 4th argument is a six-character variable (plus end of string sentinel) which must be either “radius”, “area”, or “volume” (either upper or lower case). This string determines whether the ionization fraction returned is weighted with respect to radius, area, or volume. These would be appropriate to compare to pencil beam observations, integrated long slit observations, or observations of the whole nebula, respectively. The last argument determines whether (true) or not (false) the ionization fraction is also weighted with respect to the electron density. The function returns zero if the ion was found and non-zero if an error occurred.

An ionization stage of zero will request the fraction of an element within a molecule. If the element name is “H\(^2\) “ (the letters H\(^2\) followed by two spaces) then the fraction of hydrogen in H\(^2\), \(2n(H_2)/n(H_{\text{tot}})\), will be returned. Currently only H\(^2\) is implemented.

### 8.6.12 cdLine—emission-line intensities

This finds the intensity or luminosity of any line. The label and wavelength of the line are specified and the routine returns the relative intensity and the log of the absolute intensity or luminosity. The following is an example.

```c
#include "cddefines.h"
#include "cddrive.h"
double relint , absint;
long nType=0;

if( cdLine( "totl" , 4861 , &relint , &absint , nType ) < 0 )
    printf("did not find this line\n")
```
The first argument in the call is the line label, the four-character null-terminated string (upper or lower case) used by the code to identify the line in the main emission-line printout. The second variable gives the wavelength of the line in Angstroms. Both of these must exactly match the label and wavelength used by CLOUDY to identify the line (see the chapter Lines for a full description). The third variable (relint in the above example) is a double-precision pointer to the relative intensity of the line (relative to the normalization line, usually Hβ, and reset with the normalize command). The log of the intensity (erg cm$^{-2}$ s$^{-1}$) or luminosity (erg s$^{-1}$) of the line is returned as the fourth double-precision pointer (absint in the above example). If the intensity of the line is zero or the line was not found then this variable will be set to $-37$.

The last (optional) parameter indicates which type of line prediction to return. The integer types are 0 intrinsic, 1 emergent, 2 intrinsic cumulative, 3 emergent cumulative intensities.

The intensities returned by when the last parameter is missing or it is zero are those printed with the heading Intrinsic Intensities. This does not include the effects of possible reflection off a background molecular cloud or of absorption from outside the emission-line region. If the last parameter is 1 then emergent intensities are reported. The values 2 and 3 are the equivalent quantities for the cumulative intensities in a time dependent model.

If cdLine finds the line it returns the index of the line within the stack of emission lines. So a positive return value indicates success. It returns the negative of the total number of lines in the stack if the line is not found. This may occur if the line wavelength or label was mistyped. This is an exception to the C++ function return convention in which a normal return is zero and an abnormal return is non-zero. A positive value indicates a successful return.

There is a special version, cdLine_ip, which takes the line index as the first argument and return the relative and absolute intensities as the second and their quantities. The line index is not a constant for a given version of the code. It depends on the number of elements that are included, the sizes of the iso-sequence model atoms, and whether other models like H$_2$ are included.

8.6.13 cdnZone—how many zones in the last iteration?

The routine returns the number of zones in the previous iteration.

8.6.14 cdPressure_depth—pressure structure of the last iteration

The pressure as a function of depth, for the last iteration, is obtained by calling routine cdPressure_depth. This routine has three arguments, pointers to vectors giving the total pressure, the gas pressure, and the line radiation pressure. All are double precision vectors and the calling routine must have allocated space for these before calling the routine. The total number of elements needed for each vector is the number of zones in the last iteration and is obtained by calling routine cdnZone.

8.6.15 cdPressure_last—pressure of the last zone

The pressure for the last zone is obtained by calling routine cdPressure_last. This routine has three arguments, pointers to the total pressure, the gas pressure, and the line radiation pressure. All are double precision variables. The total pressure includes all contributors to the pressure and may include magnetic, radiation, and turbulent pressure in addition to thermal pressure.
8.6.16 cdSPEC—get predicted spectrum

This routine provides an interface between CLOUDY and Keith Arnaud’s X-Ray spectral analysis program XSPEC. Depending on which option is used, it will return the incident continuum, the attenuated incident continuum, the reflected continuum, the diffuse continuous continuum, outward direction diffuse continuous emission, reflected lines, or outward lines. All are \(4\pi v J_v\) [erg cm\(^{-2}\) s\(^{-1}\)] and assume full coverage of the continuum source. Details are given in cddrive.h.

This is no longer being developed and will soon be removed. Use the save FITS command, described in Part 1, instead.

8.6.17 cdTemp—the computed mean temperature

Routine cdTemp returns the mean electron temperature weighted with respect to some species. The first parameter is a four character null-terminated string giving the first four letters (upper or lower case) of the name of an element as spelled by the code. The second parameter is the ionization stage, with 1 for the atom, 2 the first ion, etc. The third parameter will be the computed mean temperature. The last parameter is a six-character null-terminated string, either “radius”, “area”, or “volume”, that says whether the temperature should be weighted with respect to radius, area, or volume. These would be appropriate to compare to pencil beam observations, integrated long slit observations, or observations of the whole nebula, respectively. The mean temperature weighted by ion \(+n\) of element \(S\) over radius is defined as

\[
\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(l) dl}{\int n(S^{+n}) f(l) dl} \quad [K],
\]

the average over area is

\[
\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r dr}{\int n(S^{+n}) f(r) r dr} \quad [K],
\]

and the average over volume is

\[
\langle T(S^{+n}) \rangle = \frac{\int T n(S^{+n}) f(r) r^2 dr}{\int n(S^{+n}) f(r) r^2 dr} \quad [K].
\]

The routine returns 0 if it finds the species, and 1 if it could not find the species. The following is an example of a call:

```c
if( cdTemp("carb", 2, &temp, "radius") )
{
    cdEXIT(EXIT_FAILURE);
}
printf("The mean C+2 temperature is %g\n", temp);
```

An ionization stage of zero requests one of the following special temperatures. All these can be weighted by radius, area, or volume.

**21 cm-related temperatures:** The routine will return one of three temperatures related to 21 cm observations. The label “\(21\text{cm}\)” will return the mean of \(n(H^0)/T_{kin}\), the harmonic mean gas
kinetic temperature weighted with respect to the atomic hydrogen density. The label “spin” will return the mean weighted by $n(H^0)/T_{\text{spin}}$, the harmonic mean of the 21 cm spin temperature weighted with respect to the atomic hydrogen density. Finally the label “opti” returns the temperature derived from the ratio of L$\alpha$ to 21 cm optical depths (see AGN3 section 5.5).

**Molecular hydrogen:** The label “H2__” (notice that there were two spaces after the 2) and an ionization stage of zero will return the mean temperature weighted with respect to the H$_2$ density.

**Simple mean temperature:** If the label consists of four spaces, as in “ “, and the ionization stage is zero, the routine will return the mean temperature, but not weighted by any species. If the label is “TeNe” then the routine will return the mean temperature weighted by the electron density.

### 8.6.18 cdTemp_last—the temperature of the last zone

The kinetic temperature of the last zone is obtained by calling the function cdLastTemp. The function has no arguments and its return value is the temperature.

### 8.6.19 cdTimescales—several timescales.

This routine has three arguments, pointers to doubles that return the timescales [s] for several processes. These are the thermal timescale, the hydrogen recombination timescale, and the H$_2$ formation timescale.

### 8.7 Other information

#### 8.7.1 cdDate(cdString)

The date when the current version of the code was released will be placed as a null-terminated string. The string is passed as an argument and the calling program must have allocated enough room for the string.

#### 8.7.2 cdVersion(cdString)

The code’s version number will be placed as a null-terminated string into the string passed as an argument. The version number is a string rather than a float since it can end with a letter of the alphabet. The calling program must allocate enough space for the string.

#### 8.7.3 double cdExecTime()

This returns the time that has elapsed since the previous call to cdInit.
8.8 Printing comments

CLOUDY is designed to be autonomous and self aware. It constantly monitors itself to make sure that it is doing the physics correctly. After the calculation is complete, but before the emission lines are printed, it generates a series of statements that indicate warnings, cautions, comments, and surprises. These should be examined to confirm that the calculation is likely to be valid. A series of routines allows the driving code to determine whether these comments were generated, what type they were, and to print them into an arbitrary open file.

8.8.1 Were comments generated?

Routine \textit{cdNwcns} will return the number of warnings, cautions, surprises, notes, and temperature and pressure failures:

\begin{verbatim}
cdNwcns( &lgAbort, &nw, &nc, &nn, &ns, &nte, &npe, &nione, &nden )
\end{verbatim}

where the first variable is a \textit{bool} flag indicating whether the calculation aborted, \textit{nw} is the number of warnings generated (if this number is non-zero, then the calculation has serious problems), \textit{nc} is the number of cautions generated (these are less severe than warnings, but are still a cause of concern), and \textit{nn} and \textit{ns} are the number of notes and surprises. The next two arguments are the number of temperature and pressure failures. The last two are the number of ionization and electron density failures. There should not be any failures in a successful calculation.

If either of the first two variables are non-zero then the code ran into serious problems. An abort is far more serious than a warning since it indicates catastrophic failure. I would appreciate learning about these. Please post details on the code’s discussion board.

8.8.2 Printing the comments.

A series of comments normally appear after the last zone. These may be printed into any file by calling the series of subroutines described here. In all cases the routines take as an argument a file handle which must point to a file that has already been opened for writing.

\begin{verbatim}
/* output the comments into a file */
* first define the file handle, then open the file for writing */
FILE *ioOUT;
if( (IoOUT = fopen( "comments.txt", "w") ) == NULL )
{
    printf("error creating comments.txt file\n");
    cdEXIT(EXIT_FAILURE);
}
--- missing code to do calculation ---
/*print the reason the calculation stopped, and geometry*/
cdReasonGeo(ioOUT);
/*print the warnings*/
cdWarnings(ioOUT);
/*next print the cautions*/
cdCautions(ioOUT);
/*now print any surprising results*/
cdSurprises(ioOUT);
\end{verbatim}
/*now print the notes*/
cdNotes(ioOUT);
fclose(ioOUT);

**cdReasonGeo(FILE *io)** It is very important to understand why the calculation stopped. The first two lines after the last zone results give the reason the calculation stopped and the type of geometry. This information will be printed into the file whose handle is the argument.

**cdWarnings(FILE *io)** All warnings (denoted by “W-”) will be printed.

**cdCautions(FILE *io)** All cautions (denoted by a “C-”) will be printed.

**cdSurprises(FILE *io)** All surprises (denoted by a “!”) are printed.

**cdNotes(FILE *io)** The notes concerning the calculation will be printed.

### 8.8.3 cdErrors(FILE *io)—printing a summary of any problems

Routine **cdErrors(FILE *io)** will generate a summary of any problems that happened during a calculation. The argument is a pointer to the output file where the summary will be placed. The calling program must have already opened the file for writing. If problems occurred in the calculation, such as temperature or pressure failures, warnings, or cautions, will be printed along with the calculation’s title.

### 8.8.4 cdPrintCommands(FILE *io)—print the command stack

The entire series of input commands will be written into the file. The single argument is a file handle that points to a previously opened file. The commands are preceded and followed by lines that begin with “c =====” to easily identify their start and end.

### 8.8.5 setbuf or the no buffering command

Programs produce output by writing into a buffer. They only place information on the disk once the buffer is full. If a C++ program crashes before this buffer is “flushed” the information within the buffer will be lost. This poses a problem if the printout generated just before the crash is needed for debugging. The C++ io library provides a routine, **setbuf**, that can turn file buffering off. The following sequence would open a file and turn buffering off:

```c
ioDATA = open_data("test.out","w",AS_LOCAL_ONLY);
/* turn off buffering so we see results as they happen */
setbuf( ioDATA , NULL );
```

Note that the call to **setbuf** must come immediately after the call to **open_data** before any output is written. The **no buffering** command, described in Part 1 of this document, will do the same thing. Note that turning off buffering will make the code run far more slowly.
8.9 Example Call as a Subroutine

The file template.cpp shown below contains a skeleton program showing how you can call Cloudy as a subroutine. You can find the program in the directory tsuite/programs. Use this as a starting point to write your own program. The area where you can insert your own code is clearly indicated in the template.

```c++
int main(int argc, char *argv[]) {
  exit_type exit_status = ES_SUCCESS;
  DEBUGENTRY( "main()" ); // do not remove this!
  try {
    // START ENTERING YOUR CODE AFTER THIS LINE
    // inside this try block you can enter your code to call Cloudy as a subroutine
    // replace the code between here and the next ===== line with your own program
    long nleft;
    // you can call Cloudy in a loop if you want...
    for( int i=0; i < 1; ++i ) {
      // the code always needs to be initialized first
      cdInit();
      // replace this with a series of calls to cdRead to define the input script
      // this particular command line exercises the smoke test
      nleft = cdRead( "test" );
      // this calls Cloudy to execute the input script you defined above
      if( cdDrive() )
        exit_status = ES_FAILURE;
    } cdEXIT(exit_status); // always exit with cdEXIT, this assures files are properly closed.
  } catch( bad_alloc ) {
    fprintf( ioQQQ, " DISASTER - A memory allocation has failed. Most likely your computer "
             " ran out of memory.\n Try monitoring the memory use of your run. Bailing out...\n\n" );
    exit_status = ES_BAD_ALLOC;
  } catch( out_of_range& e ) {
    fprintf( ioQQQ, " DISASTER - An out_of_range exception was caught, what() = %s. Bailing out...\n\n", e.what() );
    exit_status = ES_OUT_OF_RANGE;
  } catch( bad_assert& e ) {
    MyAssert( e.file(), e.line(), e.comment() );
    exit_status = ES_BAD_ASSERT;
  } #ifdef CATCH_SIGNAL
  if( ioQQQ != NULL ) {
    if( e.sig() == SIGINT )
      fprintf( ioQQQ, " User interrupt request. Bailing out...\n" );
    exit_status = ES_USER_INTERRUPT;
    } else if( e.sig() == SIGTERM )
      fprintf( ioQQQ, " Termination request. Bailing out...\n" );
    exit_status = ES_TERMINATION_REQUEST;
    } else if( e.sig() == SIGILL )
      fprintf( ioQQQ, " DISASTER - An illegal instruction was found. Bailing out...\n" );
    exit_status = ES_ILLEGAL_INSTRUCTION;
    } else if( e.sig() == SIGFPE )
      fprintf( ioQQQ, " DISASTER - A floating point exception occurred. Bailing out...\n" );
    }
  }
}
```

--

86 CHAPTER 8. CLOUDY AS A SUBROUTINE
8.10 Computing Grids of Calculations

Today I usually use the code to compute results, extract information, and save desired quantities. The following example illustrates producing a series of models with increasing gas temperature and density. The program calculates the line strength of various diagnostic [O III] lines normalized to [O III] \( \lambda 5007 \) and writes these to a file. This example is the program \texttt{vary.nete.cpp}, which you can find in the directory \texttt{tsuite/programs/vary.nete}.

This example only saves results for a few lines. Often a large number of lines are needed. A call to \texttt{cdLineList} provides an easy way to obtain large numbers of lines whose labels are stored in a file.

/* This file is part of Cloudy and is copyright (C)1978-2010 by Gary J. Ferland and others. For conditions of distribution and use see copyright notice in license.txt */
/*main program that calls cloudy when used as a stand-alone program */
#include "cddefines.h"
#include "cddrive.h"
#include "odrive.h"

/*int main( int argc, char *argv[] ) {*/
int main( void )
{
    exit_type exit_status = ES_SUCCESS;
    DEBUG_ENTRY( "main()" );
try {
    double hdenLimit, hdenInit, hden, TeInc, 
            r5007, r4363, r1665, ro3_88, ro3_52, r1661, 
              absolute, temp, TeLimit, Tinit, hdenInc;

    FILE *ioDATA;
    char chLine[100];

    /* this is limit to the number of command chLines we can still put in */

Chapter 9

THE EMISSION LINES

9.1 Overview

The following sections outline the emission lines predicted by CLOUDY. Before version 90 of the code all lines were listed in the sub-section immediately following this section. The code is being modified to bring all lines into a common line class, as the code moves to C++ and objects. This chapter will remain incomplete until this work is finished.

9.2 The main emission-line printout

The main emission line printout was briefly described in the Chapter OUTPUT. This section goes into more detail.

Output organization. The printed list is sorted into four large groups of columns, with each large column sub-divided into four smaller sub-columns. The first sub-column is either the spectroscopic designation of the ion producing the line or an indication of how the line is formed. The second sub-column is the line wavelength, with a 0 to indicate a continuum. The third sub-column is the log of the power in the line, in the units given in the header (erg s$^{-1}$ into either $4\pi$ sr or cm$^{-2}$). The last sub-column is the intensity of the line relative to the reference line, usually H$\beta$, unless this is reset with the normalize command.

These lines can be printed as a single large column, and can be sorted by wavelength or intensity. These options are controlled by the print line command described in Part I of this document.

9.2.1 Intrinsic and emergent line intensities

The computed emission-line spectrum is divided into two groups. The first group of lines, called “Intrinsic line intensities”, gives the intrinsic intensity of the lines, and does not include the reddening effects of internal grains due to the photon’s passage out of the nebula. The second group includes the effects of grain scattering and absorption and has the header “Emergent Line Intensities”. The intensities are the total intensities observed from the illuminated face, including both absorption and scattering by grains.
9.2.2 Line identification

Line wavelengths. These are given in various units. Numbers ending in “A” are wavelengths in Angstroms (Å). For instance, Hβ is given by “H 1 4861A”. Wavelengths in microns are indicated by “m”, for example, the strong [O III] IR line is “O 3 51.80m”.

The code follows the convention that wavelengths longward of 2000Å are given in air and shorter wavelengths in vacuum. Continua are usually indicated by a wavelength of zero.

9.2.3 Blocks of lines...

Lines are organized by common origin with a comment, ending in a series of periods “...”, beginning the section. As an example, the first commented block of lines begins with “general properties...”. The following subsections give overviews of the lines.

9.2.4 General properties...

This mainly summarizes heating and cooling agents for the model.

TOTL 4861 and TOTL 1216, are the total intensities of Hβ and Lα, as predicted by the multi-level H atom. These intensities are the results of calculations that include all collisional, radiative, and optical depth effects.

Inci The total energy in the incident continuum. This entry will not be included if the aperture command is in effect.

TotH and TotC give the total heating and cooling. These will be nearly equal in equilibrium.

BFH1 and BFHx are the heating due to photoionization of ground state and excited state hydrogen respectively.

He1i, 3He1, heating due to ground state He and the triplets.

BFHe and TotM are the heating due to helium and metal photoionization.

Pair heating due to pair production.

ComH, ComC, Compton heating, cooling.

CT H CT C charge transfer heating and cooling.

extH extC “extra” heating or cooling added to model.

e-e+ 511 The positron line.

Expn, expansion, or adiabatic, cooling

H FB, H radiative recombination cooling

HFBc, HFBc, hydrogen net free-bound cooling and heating
9.2. THE MAIN EMISSION-LINE PRINTOUT

9.2.5 Continua...

These give intensities of various continua. These are either the total integrated continuum or the product $\nu F_\nu$ at certain energies.

**Continuum bands**

The file `continuum_bands.ini` in the data directory specifies a set of wavelength bands. The code will integrate over these bands to find the total radiated luminosity and enter this into the main emission-line stack. Currently this is a simple sum of the energy emitted between the upper and lower bounds of the band, and does not take into account the transmission function of particular instruments. The `continuum_bands.ini` file can be edited to change the number of bands or their detailed properties. Table 9.1 lists the bands in the file at the time of this writing. The first and second columns give the label and wavelength as they appear in the printout. The last column gives the wavelength range for the integration. These entries will not be included if the `aperture` command is in effect. Please consult the file to see its current contents and feel free to add your own bands.

**Other continua**

**Bac 3646** residual flux at head of Balmer continuum, $\nu F_\nu$. This entry will not be included if the `aperture` command is in effect.

**cout 3646 cref 3646** , outward, reflected continuum at peak of Balmer Jump. These entries will not be included if the `aperture` command is in effect.

**thin 3646** , residual flux at head of Balmer continuum, optically thin limit. This entry will not be included if the `aperture` command is in effect.

**Inci 4860, Inci 1215** , incident continua near H$\alpha$ and L$\alpha$. These entries will not be included if the `aperture` command is in effect.

**Ba C 0** , integrated Balmer continuum

**PA C 0** , integrated Paschen continuum

**HeFF 0** , He brems emission

**HeFB 0** , He recombination cooling

**MeFB 0** , heavy element recombination cooling

**MeFF 0** , metal brems emission

**Iind** , cooling due to induced recombination of hydrogen

**3He2** , cooling due to induced recombination of fully ionized helium

**Cycn** , cyclotron cooling

</table>
ToFF 0, total brems emission

FF x, part of H brems, in x-ray beyond 0.5KeV

eeff, electron - electron brems

\( nFnu 122m, nInu 122m, InwT 122m, InwC 122m \), a large list of continua at selected wavelengths will be printed if the print continuum command is entered. These entries will not be included if the aperture command is in effect. The first is the sum of various continua at the wavelength, given as \( \nu F_\nu \) (see the print continuum and set nFnu commands in Part 1 for a discussion of what is included in the nFnu entry). \( nInu \) is the transmitted and reflected incident continuum. \( InwT \) is the total reflected continuum. \( InwC \) is the reflected incident continuum.

9.2.6 Molecules...

H2dC, is the cooling due to collisional dissociation of H2.

H2dH, heating by H2 dissociation by Lyman continuum

H2vH, heating by coll deexcit of vib-excited H2

H2vC, cooling by coll deexcit of vib-excited H2

H2v, line emission by vib-excited H2

H-FB and H-FF are the free-bound and free-free continua of the H- ion.

H-CT 6563, H-alpha produce by H- mutual neutralization

H- H 0, H- heating

H-Hc 0, H- heating

H2+ and HEH+ are the cooling due to formation of H2+ and HeH+.

Codh, carbon monoxide photodissociation heating

CO C 12, C12O16 cooling

CO C 13, C13O16 cooling

9.2.7 Grains...

Information in this block concerns emission, absorption, heating, and cooling by any grains included in the calculation.

GrGH, gas heating by grain photoionization

GrTH, gas heating by thermionic emissions of grains
\textbf{GrGC}, gas cooling by collisions with grains

\textbf{GraT}, This is the total grain heating by all sources, lines, collisions, incident continuum. If the grain emission is optically thin limit then this is equal to the total intensity in grain emission.

\textbf{GraI}, grain heating by incident continuum

\textbf{GraL 1216}, grain heating due to destruction of L\(\alpha\)

\textbf{GraC}, grain heating due to collisions with gas

\textbf{GraD}, grain heating due to diffuse fields, may also have grain emission

Grain emission is included in the predicted total emitted continuum. A machine readable form of the continuum can be produced with the \texttt{save continuum} command, also described in Part I of this document.

\subsection*{9.2.8 \textbf{H-like iso-seq. . .}}

This block includes all hydrogen-like isoelectronic species. The \texttt{atom H-like} command, described in Part 1 of this document, adjusts properties of this sequence.

\textbf{HFFc 0}, net free-free cooling, nearly cancels with cooling in lte

\textbf{HFFh 0}, net free-free heating, nearly cancels with cooling in lte

\textbf{H FF 0}, H brems (free-free) cooling

\textbf{FF H 0}, total free-free heating

\textbf{Clin 912}, total collisional cooling due to all hydrogen lines

\textbf{Hlin 912}, total collisional heating due to all hydrogen lines

\textbf{Cool 1216}, collisionally excited La cooling

\textbf{Heat 1216}, collisionally de-excited La heating

\textbf{Crst 960}, cooling due to \(n\leq2\) Lyman lines

\textbf{Hrst 960}, heating due to \(n\leq2\) Lyman lines

\textbf{Crst 4861}, cooling due to \(n\leq3\) Balmer lines

\textbf{Hrst 4861}, heating due to \(n\leq3\) Balmer lines

\textbf{Crst 0}, cooling due to higher Paschen lines

\textbf{Hrst 0}, heating due to higher Paschen lines

\textbf{LA X 1216}, L\(\alpha\) contribution from suprathermal secondaries from ground
9.2. THE MAIN EMISSION-LINE PRINTOUT

\textbf{Ind2 1216}, L\alpha produced by induced two photon

\textbf{Pump 4861}, H\beta produced by continuum pumping in optically thin \textit{ld} limit

\textbf{CION 0}, net col ionz-3 body heat collision ionization cooling of hydrogen

\textbf{3bHt 0}, heating due to 3-body recombination

\textbf{Strk 1216}, Stark broadening component of line

\textbf{Dest 1216}, part of line destroyed by background opacities

\textbf{Fe 2 1216}, part of L\alpha absorbed by Fe II

\textbf{Q(H) 4861} is the intensity of H\beta predicted from the total number of ionizing photons, Q(H\textsubscript{0}), assuming that each hydrogen-ionizing photon produces one hydrogen atom recombination. This entry will not be included if the \texttt{aperture} command is in effect.

\textbf{Q(H) 1216} indicates the L\alpha intensity produced if each hydrogen ionizing photon results in one L\alpha photon in the high density limit (i.e., no two-photon emission). This entry will not be included if the \texttt{aperture} command is in effect.

\textbf{CaBo 4861} These are the “old” case B predictions, as printed in versions 90 and before of the code.

\textit{Ca B 6563A} The entries starting with “Ca B” are the Case B intensities computed from the actual model ionization and temperature structure, but assuming that H\beta emits with its Case B emissivity.

Next the predicted intensities of all lines of the hydrogenic iso-electronic sequence are given. The lines have labels that identify the species and stage of ionization, such as “\textit{H 1}”, “\textit{He 2}”, “\textit{Li 3}”, “\textit{C 6}”, etc. The entries with a wavelength of zero are the total intensities of the \textit{2s – 1s} two-photon emission.

9.2.9 \textbf{He iso-sequence...}

Atoms and ions of the helium-like iso-electronic sequence are treated as multi-level atoms. All species and stages of ionization are specified by labels like “\textit{He 1}”, “\textit{Li 2}”, “\textit{C 5}”, etc. A wavelength of zero indicates the two-photon continuum. The \textit{2 \textit{3P}} term is resolved into three levels. Emission of each line of the \textit{2 \textit{3S} – 2 \textit{3P}} and \textit{1 \textit{1S} – 2 \textit{3P}} multiplets is predicted along with the sum of the multiplets with label “\textit{TOTL}”. The \texttt{atom He-like} command, described in Part 1 of this document, adjusts properties of this sequence. Further details are given in \textit{Bauman et al. (2005), Porter et al. (2005), and Porter and Ferland (2007).}
9.2.10 level 1 lines...

In the current version of the code, the lines printed under this title include both the lines that have been moved to the EmLine class, but also older lines that are still scalar quantities. This part of the code is still in a state of flux, and this is reflected in the current documentation. The remaining part of this subsection outlines the methods used for most of the heavy element atoms. The method for producing a list of transferred lines, those that have been moved to the EmLine class, is described in the section beginning on page 99 below.

These lines have accurate collision strengths and wavelengths. Many are two-level atoms, but some are the result of multi-level atoms. The following is a summary of the general approach.

Li-sequence. Examples include C IV $\lambda 1549$, O VI $\lambda 1034$, and Mg II $\lambda 2798$. A three-level atom, with full treatment of optical depths and collisional excitation, is used. The “TOTL” intensity is the sum of both lines in the doublet, and is followed by the individual intensities of each member.

Be-sequence. Examples include C III] $\lambda 1909$, O V] $\lambda 1215$, and Si III] 1895. A four-level atom, solving for populations of the individual $3P_j$ states, is used. The first printed intensity is the total intensity of the multiplet (both $j = 0, 1$ decays) and this is followed by the intensities of individual lines. The intensity of the permitted $1P_0 - 1S$ transition is also calculated. Optical depth and collisional effects on both the permitted and intercombination lines are included.

B-sequence. Examples include C II and O IV. The ground term is treated as a two level atom, with optical depth and collisional effects included, when the gas is too cool to excite the UV lines. The $4P - 2P_0$ lines are also predicted with a full multi-level atom that resolves fine structure. The “TOTL” intensity printed is the total intensity of the multiplet and is followed by individual lines. Pumping by all level-two lines of the same ion is included as an excitation process.

$3P$- ground term. Examples include such spectra as [O III] and [O I]. The infrared fine structure lines are computed with full treatment of collisional and optical depth effects. A comment is printed at the end of the model if these lines mase or become optically thick. The populations of $1D$ and $1S$ are computed with a three-level atom. The intensity of the $1D - 3P$ transition is only that of the individual line (i.e. 5007), not the doublet.

$4S^0$ - ground term. Examples include [O II] and [S II]. They are treated as a five-level atom. Intensities of all individual lines, as well as co-added multiplets, are given.

9.2.11 Recombination...

These are a set of heavy-element recombination lines that are predicted in the low-density limit assuming that the transitions are optically thin. This consists of all recombination lines of C, N., and O, with coefficients taken from Nussbaumer and Storey (1984) and Pequignot et al. (1991).

These predictions are for optically thin pure recombination. These should be accurate for planetary nebulae and H II regions. They will not be accurate for dense environments where optical depths and collisional effects come into play. These are only included in the output if the electron density is less than $10^8$ cm$^{-3}$, a rough upper limit to the range of validity in the original calculations of the coefficients.

There are several instances where more than one line of an ion will have the same wavelength due to the integer Angstrom format used for wavelengths. The worst case is O V 4953, where three lines of the same multiplet have the same wavelength.
9.2.12 Level 2 lines...

These are resonance lines that use Opacity Project wavelengths, which are generally accurate to about 10%. These lines have g-bar collision strengths, which are not very accurate at all.

9.3 The transferred lines

9.3.1 Save line data output

The group of “transferred lines” includes all those that have been moved to the EmLine class.

In older versions of this document a large list of emission lines appeared here. This list is now far too large to include here. Rather, the list can be generated by executing the code with the command `save line data “filename.txt”` included. This will create a file that includes the full set of lines that are predicted. Note that the lines that are output are only those that exist when the code is run. It is possible to make many of the model atoms and molecules as large or small as you like, and the actual lines that exist when the `save` command is entered will be output. The test case `func_lines.in` in the test suite includes this save command and generates a list of all transferred lines in the file `func_lines.lis`.

To generate a line list, set up a calculation with the atoms set to whatever size is desired (see the `atom` command in Part I). Then execute this script with the `save line data` command included (described in Part I). The save output will include the line list. This will include the level 1, level 2, H\textsubscript{2}, Fe II, CO, and recombination lines, but not the scalar forbidden lines. These are described in a list following this subsection.

This contains several groups of lines. All quantities were evaluated at 10\textsuperscript{4} K. The description of the command in Part I of this document explains how to evaluate the quantities at other temperatures.

The ion is the first column of the table. This is in a uniform format, beginning with the two character element symbol and followed by an integer indicating the level of ionization. “C 2” is C\textsuperscript{+} or C II. This is followed by the integer wavelength label used to identify the line in the printout. The third column, with the label “WL”, is the correct wavelength of the line, with units of microns (“m”), Angstroms (“A”), or cm (“c”). The remaining columns give the statistical weights of the lower and upper levels, the product of the statistical weight and the oscillator strength, and then the transition probability.

The last column is the electron collision strength. Usually these collision strengths are for only the indicated transition, although in some cases (the Be sequence) the value is for the entire multiplet.

9.3.2 Output produced for the transferred lines

Because the lines have a common format within their storage vectors, the output has a common format too. Generally only the total intensity of the transition, the result of the solution of a multi-level atom with all processes included, is printed. The approach used to compute the level populations is described in Part II of HAZY, and includes continuum pumping, destruction by background opacities, and trapping.
The total intensity of the transition is printed in a form like “C 2 1335”, with the spectroscopic identification given by the first part, as found in the first column of the table, and the wavelength as indicated by the number in the second column of the table.

In a few cases (for instance, the C IV $\lambda \lambda$ 1548, 1551 doublet), a total intensity is also derived. In these cases the label “TOTL” will appear together with an average wavelength (1549 in this case). These lines are all explicitly shown in a following section.

It is possible to break out various contributors to the lines with options on the print line command, described in Part I of this document and in the following. These contributors are printed following the total intensity.

- **print line heating** An emission line will heat rather than cool the gas if it is radiatively excited but collisionally de-excited. The print out will include this agent, with the label “Heat”, when this command is given.

- **print line collisions** The collisional contribution to the lines will be printed, with the label “Coll”.

- **print line pump** The contribution to the total line, produced by continuum pumping, is printed with the label “Pump”. What is observed? Whether or not this is a net emission process contributing to the observed line intensity depends on the geometry, mainly whether or not continuum source is in the beam. At some velocities within the line profile this can be a net emission process, due to absorption at other velocities. If the continuum source is in the beam and gas covers it, this is not a net emission process, since photons are conserved.

- **print line inward** The inwardly directed part of the total emission is printed with the label “Inwd”. This can be greater than half of the line intensity if the line is optically thick since these lines tend to be radiated from the hotter illuminated face of the cloud.

- **print line optical depths** At the end of the calculation the optical depths for all optically thick lines will be printed. This is not done by default since it can be quite long.

### 9.4 Line identifications

The file `line_labels.txt` in the docs directory of the distribution lists line identifications and a brief description of its origin.

### 9.5 Hydrogen recombination lines

Table 9.2 gives the strongest lines of the lowest series. All lines have the label “H 1”. The wavelength column gives the string as it appears in the printout. “m” indicates a wavelength in $\mu$m and A in Angstroms. The Case B intensity is taken from the limit_caseb_h_hs87 test case.

Some IR lines may have the same wavelength if the default line precision is used. The set line precision command can be used to increase the number of significant figures in the line wavelength, which should make identification easier.

9.6 Molecular hydrogen lines

Table 9.3 gives some of the stronger or more frequently observed \( \text{H}_2 \) lines. These are only predicted when the large model \( \text{H}_2 \) molecule is included with the atom H\( \text{H}_2 \) command. The wavelength column gives the string as it appears in the printout. “m” indicated a wavelength in \( \mu \text{m} \). All lines have the label “H\( \text{H}_2 \) ”.

Many lines will have the same wavelength if the default line precision is used. The set line precision command can be used to increase the number of significant figures in the line wavelength, which should make identification easier.

The following is an example which predicts the emissivity of the \( \text{H}_2 \) 2.121 1-0 S(1) \( \mu \text{m} \) line.

```plaintext
save line emissivity 'lines.ems'
H2 2.121m
end of lines
```

A list of all \( \text{H}_2 \) lines with their labels and excitation energies can be generated with the command save H\( \text{H}_2 \) lines. The Joint Astronomy Centre in Hawaii give a summary of \( \text{H}_2 \) lines.

9.7 CO lines

Rotation transitions within the ground vibration level are included. These are listed in Table 9.4 which gives the symbol “m” to indicate \( \mu \text{m} \).

Chapter 10

PROBLEMS

10.1 Introduction

The code is designed to be autonomous and self-aware. Nonetheless, if can run into problems. This section describes some of the errors that can cause CLOUDY to stop. Floating point errors should never occur. Several other internal errors, which the code is designed to trap and then complain about, could occur. Finally, it is possible that the code will stop because of convergence problems.

The most important single thing to understand about any calculation is why it stopped and whether this affects the predictions. This is discussed further in the section Stopping Criteria.

If the calculation aborts it will conclude with a request to post the information on the web site’s discussion board—please do—we can’t fix it if we don’t know it’s broken.

Please post any problems on the discussion board on the code’s discussion board.

10.2 Thermal stability and temperature convergence

This section describes thermal stability problems, how to identify them, and what to do about them.

10.2.1 Types of thermal maps

Three types of thermal maps, showing the heating or cooling of gas as a function of temperature, can be produced by CLOUDY. Each is the answer to a different question.

Figure 10.1 shows the heating and cooling rates as a function of temperature for a photoionized gas in which the gas kinetic temperature was varied. This figure was produced with the test case func_map.in, one of the standard test cases included in the code distribution. Both the gas density and the flux of ionizing photons were held constant and the kinetic temperature was varied. Only one temperature, the point where the two curves cross, occurs in equilibrium. The func_map.in file uses the save map command to determine heating and cooling rates at a variety of temperatures. This is exactly what the code does to determine the equilibrium temperature, so this plot can be useful to find out why the code ran into temperature convergence problems. This is why the command was introduced.
Figure 10.1: A typical heating—cooling function for low density photoionized gas. The cooling and heating rates (erg cm\(^{-3}\) s\(^{-1}\)) are shown.
Collisionally-ionized gas has a well-defined cooling rate that is only a function of temperature. The sample program hazy_coolingcurve.cpp (included in the programs directory in the code’s distribution) does such a calculation, and Figure 10.2 shows the results. Here the kinetic temperature is set by some physics external to the calculation. The entire ionization solution is valid for each temperature under this assumption. The unspecified heat source would have to provide a local heating rate that is equal to the calculated cooling rate for the solution to be time steady.

The third map is the type of thermal stability map shown by Krolik et al. (1981) and plotted in Figure 10.3. The program that generated these results is given in the file hazy_kmt.cpp. Here the equilibrium temperature is determined self-consistently for gas over a wide range of densities, but for a single flux of ionizing photons (or equivalently, distance from the central object).

### 10.2.2 No Temperature Convergence

A temperature failure occurs when the heating-cooling balance is not within a certain tolerance, set by the set temperature error command, after 20 tries. Normally CLOUDY will punt after an excessive number of temperature failures occur. The limit to the number of failures is reset with the failures command. If the failures map command is entered then the code will first produce a
Figure 10.3: Equilibrium temperature as a function of density.
map of heating-cooling space to give an indication of where the equilibrium temperature should have been when excessive failures occur.

Temperature failures most often occur for temperatures in the range \(10^2\) K to \(4 \times 10^3\) K, and \(10^5\) K to \(10^6\) K. These are where the cooling function permits more that one thermal solution (see, for example, Williams, 1967; Dalgarno and McCray, 1972).

Figure 10.1 shows a typical cooling function for gas in photoionization equilibrium. A peak is reached at a temperature near \(10^3\) K. This occurs when the fine-structure lines are major coolants. At lower temperatures their cooling rate increases exponentially (as expected), until roughly \(10^3\) K, when their Boltzmann factors are near unity. Above this temperature their cooling rate is nearly proportional to the Coulomb focusing factor \(T^{-1/2}\), and the cooling decreases until the temperature is high enough for optical forbidden lines to become important (at roughly 4000 K). A similar phenomenon occurs near the \(\sim 10^5\) K to \(10^6\) K peak in the cooling function.

When failures occur because more than one temperature solution is possible, the reported failures are a physical (not numerical) problem. CLOUDY will try to deal with this by forcing the temperature to values below the peak in the cooling function. Increasing the number of allowed failures (with the failures command) to prevent the code from stopping prematurely is permissible as long as the global energy balance is preserved. A warning will be issued at the end of the calculation if the heating-cooling balance is not preserved.

10.2.3 Thermal Stability

The thermal solution may be unstable when the temperature derivative of the net cooling function (cooling minus heating) is negative (Field, 1965). Possibly unstable solutions are indicated by a “u” just before the equilibrium temperature in the zone printout. The temperature derivative is for isochoric (constant density), not isobaric (constant pressure), conditions. Comments are printed at the end of the calculation if possibly unstable thermal solutions are present in the calculation.

10.2.4 Thermal fronts

Just as an ionization front is a region where the level of ionization changes dramatically over a small scale, a thermal front occurs where the temperature changes dramatically over a small scale. This can be caused by a real physical change of state of the gas such as those that occur near the peaks in the cooling curve. An example of a thermal front, taken from Ferland et al. (2002), is shown in Figure 10.4. This type of jump is physical. The gas changes phase and moves to different branches of the cooling curve. The code will generate a caution or comment if the electron temperature changes discontinuously from one zone to the next.

A thermal front can lead to pressure convergence failures when the solution jumps between the high and low temperature branches. Figure 10.5 shows an example case, taken from orion_hii_pdr_pp.in in the test suite. This shows the pressure history (output with the save pressure history command). The solver adjusts the density trying to make the resulting pressure agree with the desired pressure. The pressure changes continuously with density up to the point where the temperature jumps over the peak in the cooling curve. No solution is possible, and the code announces a pressure failure. In nature the presence of a magnetic field (added with the magnetic field command) will cushion the front from large changes in density.
Figure 10.4: An example of a thermal front in a cooling flow cloud (Ferland et al., 2002). The x-axis is the depth into the cloud (cm). The thermal front at $\sim 4 \times 10^{15}$ cm is unresolved.

Figure 10.5: A thermal front in a constant pressure simulation. The x-axis gives the density [cm$^{-3}$] and the y-axis is the pressure [dynes cm$^{-2}$]. The points forming the large box are the resulting total gas pressure and the horizontal line is the correct pressure. The solution jumps above and below the equilibrium value as the temperature jumps above and below the thermal front.
Figure 10.6: A constant-pressure thermal front in a temperature-radius plot. The x-axis gives the radius (cm). The y-axis gives the log of the temperature (K). The solution jumps above and below the equilibrium value, leading to a series of pressure failures, near a depth of $2 \times 10^{17}$ cm, as it soldiers on through the thermal front.

A serious of pressure failures occur in this simulation when the gas falls to a temperature of $\sim 300$ K, as shown in Figure 10.6. The code simply presses on with the goal of reaching the cold side of the front.

### 10.2.5 Map Output

The program stops if an excessive number of temperature failures occur. The default limit is 20. It will produce a map of the heating and cooling as a function of temperature for the last computed zone if the map option on the failures command is given. The map is described here. The start of the output from the test case func_map.in is shown below.

```
90.02x map of heating vs cooling
te, heating, cooling.
Cloudy punts, Te= 9.254E+03 HTOT= 9.123E-24 CTOT= 9.118E-24 nzone= 1
COOLNG array is
  O  4  25  0.340  O  3  5007  0.182  O  3  88  0.075  H FB  0  0.057  S  4  10
  H  ff  0  0.022  S  3  33  0.020  Ne  3  15  0.019  He fb  0  0.015  N  3  57
  Ne  5  24  0.010  Ne  5  14  0.009  C  3  1910  0.008  He ff  0  0.007  S  2  34
Line heating array follows
  Te  Heat-----------------> Cool-----------------> dH/dT  dC/DT
1.0000E+01  3.4774E-22  1  1  0.636  4.6095E-26  H FB  0A  0.723  -8.19E-24  1.56E-27  9.1
1.0209E+01  3.4490E-22  1  1  0.635  4.6814E-26  H FB  0A  0.720  -7.98E-24  1.65E-27  9.1
1.0423E+01  3.4233E-22  1  1  0.635  4.7510E-26  H FB  0A  0.717  -7.74E-24  1.74E-27  9.1
```

The output begins with a listing of the strongest coolants for the last zone. Then the program steps through increasing temperatures and prints the heating, cooling, and ionization of the gas.
CHAPTER 10. PROBLEMS

From this information it should be possible to determine the temperature where the equilibrium thermal solution should have been. Each solution is completely self-consistent, except that heating and cooling do not balance. Both the local attenuated radiation field and collisional ionization contribute to the ionization balance at each temperature. All processes contribute to the thermal balance, including collisional ionization. The map is at constant density.

The first column gives the temperature. Columns 2 and 6 give the volume heating and cooling. Both have units erg s$^{-1}$ cm$^{-3}$. Columns 3 and 4 constitute an indication of the main heating source. Columns 7 and 8 give the label and wavelength of the strongest coolant. Columns 5 and 9 give the fraction of the total heating or cooling due to these agents. Columns 10 and 11 give the heating and cooling derivatives. Columns 12 and 13 give the electron and hydrogen densities (cm$^{-3}$) and the remaining columns give the logs of the hydrogen and helium ionization fractions. The location of the probable thermal solution is indicated by a comment surrounded by dashed lines.

10.3 Convergence problems with dust-free static sphere

Ionization convergence problems can occur with a dust-free static spherical geometry. The default geometry when the \texttt{sphere} command is entered is for lines to freely escape after crossing the central hole due to some level of expansion. In a static spherical geometry (set with the \texttt{sphere static} command) the total L$\alpha$ optical depth at the illuminated face of the shell will be very large since the line is scattered by the matter that lies across the entire shell. The line is destroyed when dust is present. If dust is not present the L$\alpha$ intensity $J$ will become very large. If the total optical depth in L$\alpha$ is also large then the dominant escape / destruction process for the line will be absorption by atoms of third-row elements or the $n = 2$ level of hydrogen. This can lead to ionization convergence problems due to the extremely large L$\alpha$ intensity $J$.

The first question to ask is whether this geometry is appropriate. Dust is nearly always present in the ISM. In dense stellar environments it is unlikely that a spherical geometry will be static. Include dust, use the default expanding spherical geometry, or a wind, and the problem will go away. To the best of my knowledge this geometry does not occur in nature.

10.4 Optical depth convergence problems

The code generally will not converge if it has not done so within ten or so iterations. Convergence problems most commonly occur when the specified column density or thickness is very near a prominent ionization front. In this case very small changes in the physical conditions result in large changes in the optical depths. The code will not have convergence problems if an optical depth is used as a stopping criterion instead.

10.5 Negative populations

It is possible that the code will stop because negative level populations were predicted for atoms, ions, or molecules. This is not supposed to occur, but sometimes happens because of numerical
instabilities in the matrix inversion routine. Please post the input stream and version of CLOUDY on the code’s discussion board.

10.6 Floating Point Errors

The code should be compiled and linked with options enabled so that the code will crash on overflow or division by zero, but ignore underflow. The crash command described in Part 1 tests this. Floating point errors should never occur. The logic within the code is designed to identify problems, and complain, but not fail. The logic is only as good as the tests they were designed to pass. It is inevitable that circumstances will occur for which the logic now in the code is not sufficient. It is possible that the code will fail when these circumstances occur. I would be grateful for reports of any such failures, since they inevitably identify shortcomings in the code, and lead to its improvement. Please post comments on the discussion board on the code’s web site.

10.7 We can’t fix it if we don’t know it’s broken

Machines are growing faster far more rapidly than people are getting smarter. Reliability in the face of complexity is the major challenge to the development of any large-scale computer code (Ferland, 2001). There can be little doubt that CLOUDY contains bugs.

If problems arise or the code crashes then it is likely that you found a problem. We would appreciate learning about such problems since they identify shortcomings which usually lead to improvements in the code (or the documentation). Please post queries and bug reports on the discussion board on the code’s discussion board.
Chapter 11

HISTORY AND ACKNOWLEDGEMENTS

11.1 History

CLOUDY was born at the Institute of Astronomy, Cambridge, in August of 1978, in the computing environment described in the web document http://www.nublado.org/gary/computing1970s.htm. Its development has been continued at The University of Kentucky, The Ohio State University, and during extended visits to the Joint Institute for Laboratory Astrophysics, the Royal Greenwich Observatory, IOA Cambridge, Cerro Tololo Interamerican Observatory, and the Canadian Institute for Theoretical Astrophysics.

The code has been through three computer languages. It was originally written in FORTRAN IV and advanced through several dialects, reaching FORTRAN 77 in 1994 (version 84). Version 90 was written in a mix of FORTRAN 77 and MILSPEC extensions. This was the most advanced Fortran that could be used with open source compilers. It moved to ANSI 89 C in 1999 (version 96) and to C++ with the release of 07.02 in 2007.

Moore’s Law is due to Gordon Moore, one of the founders of Intel Corporation. He observed that modern CPU’s become about twice as powerful every 18 months. This trend has held true for the past twenty years, shows no sign of failing, and seems to be associated with our ability to control complexity. By this standard the growth of CLOUDY has been conservative, in that it is growing slower and complex on the Moore’s-law timescale. Figure 11.1 shows the evolution of the code, as indicated by its size as a function of time.\footnote{Before mid-1995 the size was the total number of lines in the distributed source. After 1995 the size only includes the number of lines excluding block data. When the code was converted to C the block data were converted to external data files. These external files are now far larger than the code itself.} As another example, the Meudon 1985 Meeting planetary nebula test (pn.paris.in in the test cases) has always taken about one minute to compute.

11.2 Acknowledgments

Comments or suggestions which led to the improvement of CLOUDY were made by the many individuals acknowledged on the web site http://www.nublado.org.

Peter G. Martin and Hagai Netzer had special roles during the early development of the code. Peter added several of the commands that deal with ordering of supplemental line lists and the
Figure 11.1: The size of the code as a function of time. The code grows roughly 7% larger per year, with growth spurts and slowdowns at times. There are several changes in slope evident - the year and cause are: 1985 - mainframe to Unix; 1993 - Unix to windows; the jump at 1999 - the Fortran to C conversion and the Williams / van Hoof drop in 2006, due to the use of object-like structures and moving converted fortran block data into separate files.
luminosity options on the **blackbody** command, insisted that CLOUDY run on a VAX, provided access to the University of Toronto VAX 11/780 during the 1980’s, and more recently hosted the group at CITA during a sabbatical. Hagai and I have spent countless hours arguing over methods, assumptions, and just whose code had the bug. These comparisons are the only way to debug codes as large as CLOUDY or ION.

Peter van Hoof has gone over the code very carefully, finding many problems, and expanding its capabilities. The current version of the grain physics was developed by Peter together with Peter Martin, and Joe Weingartner. PvH developed the stellar library implementation in the current version. He is the maintainer for both the grains and stellar atmospheres codes.

The move to make the solvers far more rigorous and include dynamics and advection has been led by Robin Williams and Will Henney. Robin has rewritten the chemistry solvers to take advantage of the structures present in the C language and make them more robust.

The initial implementation of the hydrogen iso-electronic sequence was done by Jason Ferguson as part of his thesis. Ryan Porter developed the He-like isoelectronic sequence in his thesis. The expansion of the simulations into the PDR was done by Nick Abel and Gargi Shaw as part of their theses.

Sections of the code are taken from public domain software, as acknowledged in this document and in the source. Portions of the code were written by those listed in the `others.txt` file in the distributed files.

The preparation of the bibliographic references in this document made use of data from the NASA’s Astrophysics Data System Bibliographic Services.

The development of CLOUDY would not have been possible without twenty nine years of continuous support by The National Science Foundation. This began with AST 80-2522, and has been continued with grants 83-05094, 85-12414, 87-19607, 90-19692, 93-19034, 96-17083, 00-71180, 03-0772, and most recently AST 06-07028. NASA has supported CLOUDY through ATP program awards NAG5-12020 and NNG05GD81G. Support from the University of Kentucky Center for Computational Sciences is also gratefully acknowledged.
Appendix A

ATOMIC DATA SOURCES

Codes like CLOUDY can only exist because of the large body of work done by the atomic and molecular physics community. This work will only continue to be supported if it is cited in the literature whenever it is used. The following is a partial list of citations for the atomic data used within the code.

This table is generated by the perl script doc.atomic_data.pl. This generates the file doc.atomic_data_refer.txt which is pasted below.
APPENDIX A. ATOMIC DATA SOURCES
### Appendix B

**GLOSSARY OF SYMBOLS**

As far as possible, the notation used by H\(AZY\) follows standard texts (AGN3; Mihalas, 1978). This is a summary of some of the symbols used.

The fundamental constants used by the code are from the CODATA recommended values. Constants are contained in the header `physconst.h`.

CONVERSION FACTORS

Table C.1 gives conversion factors between various common units. The last column of the table gives the variable names for constants that occur within the code. Most are defined as macros within the header file physconst.h. These should be used instead of entering the constant directly. In the following all Rydbergs are for infinite mass nuclei.

The fundamental constants used by the code are from the CODATA recommended values and are in the header file physconst.h. Derived quantities should be formed from the fundamental quantities given there, so that any future changes will trickle down into all parts of the code.

THE TEST SUITES

D.1 Introduction

The code must be completely tested every time anything is changed. This is done with the test suite that is included in the distribution. The following pages list the test cases included in the auto directory within the test suite directory tsuite.

The test suite contains a series of Perl scripts that automate several tasks. The readme_tests.htm file included with the tests describes these scripts. The script doc_tsuite.pl extracts the test names and the description of each, and creates two files, doc_tsuite.htm, a formatted description of each test, and doc_tsuite.txt, the table that follows this discussion.

The test cases include a large number of monitor commands that allow the code to be automatically tested every night. These monitor commands have been removed from the examples below.

The simulations form various classes. The names of the classes and their intention is given in Table D.1.

D.2 Organization of commands

Commands can occur in any order but we have made an effort to enter them in the following order. This is so that they can be studied to see examples of how to use the code.

- c commands controlling continuum
- c commands for density & abundances
- c commands controlling geometry
- c other commands for details
- c commands controlling output As indicated, there are the print and save commands which control the code’s output.
- c commands giving the monitors Each test includes a number of monitor commands. These give values of predicted quantities that the code has obtained in the past. Changes to the code may cause predicted values to change, and if they do the monitor command will announce it.
Table D.1: Keywords used in the Test Suite.

This model computes the albedo of a fairly standard BLR cloud. This is the type of model that was presented in the BLR albedo paper by Korista & Ferland, 1998, ApJ 495, 672.

The print diffuse continua command enters continuum fluxs into the emission line stack. The asserts then check that these continua have the expected brightness.

=======================================
c

This is a model of the Compton reflector in AGN. It is a constant temperature since models of this region
often make that assumption. A plot in Part I of Hazy shows the incident and reflected portions of the
continuum. The code will complain that the cloud is Compton thick since it is not really designed to simulate
this situation.

this is a simple warm absorber model. It makes a plot of the transmitted continuum, and generates a list of lines with significant optical depths

---

**aperture_beam_int**  *test aperture beam command with intensity*

This is a homogeneous sphere that is especially simple. The model is a test of the aperture command, a command that simulates observing part of an extended object. In this case the aperture is a beam centered on the center of the nebula, with a line of sight extending through the object.

The code carries along a dummy emission line ("Unit 1") with a constant intensity of $1 \times 10^{-10}$ erg cm$^{-3}$ s$^{-1}$. The line goes through all of the code's infrastructure, and when the calculation is complete, the program confirms that the "luminosity" of the line is the emitting volume times $1 \times 10^{-10}$. The aperture command is verified by asserting that the emission line has the correct "luminosity". In this case the inner radius is not specified so the returned value is unity.

---

**aperture_beam_lum**  *test aperture beam command with luminosity*

This is a simple warm absorber model. It makes a plot of the transmitted continuum, and generates a list of lines with significant optical depths

c=======================================
c

This is a homogeneous sphere that is especially simple. The model is a test of the aperture command, a command that simulates observing part of an extended object. In this case the aperture is a long slit centered on the center of the nebula, extending beyond the outer reaches of the matter.
The code carries along a dummy emission line ("Unit 1") with a constant intensity of 1e-10 erg cm^{-3} s^{-1}. The line goes through all of the code's infrastructure, and when the calculation is complete, the program confirms that the "luminosity" of the line is the emitting volume times 1e-10. The aperture command is verified by asserting that the emission line has the correct "luminosity".

This is similar to one of the BLR models presented in Ferland et al. (1992) for the well-studied Seyfert galaxy NGC 5548. It has a very large column density and is marginally optically thick to electron scattering. The spectrum is given relative to Lya, and the intensity of this line is reset to produce a spectrum that is on the same intensity scale as that paper.

Ferland and Persson (1989) presented this calculation of a BLR cloud. The differences between the present predictions and those given by FP are largely due to improved treatment of Balmer line escape and destruction. The spectrum is given relative to a Lya intensity of 100. The column density is VERY large, to reproduce intensities of low-ionization lines, especially the Ca II lines.

blr_hizqso high Z quasar cloud

stop column density 21
c
other commands for details =========
c
once elec den fail occurs due to tripping over He+ - He I-front
code does recover so not a problem. The default for this is 10,
cand is set low because (hopefully) this would never occur
chydrogen is a minor constituent in this high metallicity gas
cthe electron density is well above the hydrogen density
This is a model of a very high metallicity BLR cloud. It checks the intensities of some of the bright lines, and is a check that the code can converge a cloud with this high Z.

Secondary ionization is very important when H is highly ionized, due to very high He abundance. Secondary ionization becomes important at the He+ - He ionization front, where H+/H is 1e-5.

This is the "standard" BLR model presented by Kwan and Krolik (1981).

Compare line intensities to previous versions of CLOUDY by entering into table on page Error! Bookmark not defined..

The code caution that the resulting total pressure was not constant is to be expected. The KK calculation assumed constant gas pressure, but internally generation line radiation pressure is significant. Because of this the sum of gas plus radiation pressure was not constant although the gas pressure was.

This is an example of a "conventional" BLR calculation. The parameters are similar to those of Table 1 of Netzer and Ferland (1984). Notice that the ratio of Lyalpha to Hbeta ratio is much larger than observed.

This is the lower density cloud computed in Rees et al. (1989). Table 1 of that paper lists the predictions, which were a mean of those of Hagai Netzer's ION and roughly version 76 of CLOUDY. The lines are generally still in good agreement with the predictions of that paper. In particular the changes in the line fluxes shown in Figure 1 of that paper are reproduced quite well.

This is the lower density cloud computed in Rees et al. (1989). Table 1 of that paper lists the predictions, which were a mean of those of Hagai Netzer's ION and roughly version 76 of CLOUDY. The lines are generally still in good agreement with the predictions of that paper. In particular the changes in the line fluxes shown in Figure 1 of that paper are reproduced quite well.
This is a very dense cloud, and was computed in Rees et al. (1989). Table 1 of that paper lists the predictions, which were a mean of those of Hagai Netzer's ION and roughly version 76 of CLOUDY. The lines are generally still in good agreement with the predictions of that paper. In particular the changes in the line fluxes shown in Figure 1 of that paper are reproduced quite well. The fluxes of Lya and Hb are not reproduced with great precision by this model because of changes in collision rates for hydrogen and especially the form of the escape probability function for subordinate lines. As Figure 1 of RNF showed the line intensities are very sensitive to density for these parameters.

This tests conditions of collisional equilibrium at low densities. This is one of a series of sims coll_t?.in which test ionization over a range of temperatures. This one, unlike the others, includes cosmic rays. Chemistry is important at this low temperature and the chemical network will collapse without a source of ionization. The cosmic rays provide this source of ionization.

This is a model similar in spirit to the blister geometry H+ region model computed by Baldwin et al. (1991), but with a D-critical flow. Many physical processes have been disabled to make this simulationn faster. Grain physics is not done so the gas temperature is incorrect. The main purpose is to do a quick test of the dynamical flow with grain opacities included. The slow directory contains a full simulation of a flow like Orion.

c commands for density & abundances =========
hden 4
this only includes H and He
file://C:/Users/gary.CLOUDS/Cloudy/trunk/tsuite/auto/doc_tsuite.htm

This tests the radiative acceleration and terminal velocity of a wind in which only electron scattering is important. The parameters were chosen so that electron scattering is the dominant opacity source, so that the equations can be solved both numerically (in the example) and analytically (the expected solution given above). In a realistic wind the gas would be more neutral and line driving would dominate. The force multiplier, given in the punch wind output, is nearly unity as a result.

Checks:
- The radiative acceleration is correct ($e^{-9.5439}$ cm s\(^{-2}\)).
- The terminal velocity should be 7.57 km s\(^{-1}\).
- Force multiplier near unity (no line driving since so highly ionized).
- Thickness of cloud correct ($R - R_0 + \frac{dr}{2}$ should be 3.086391017 cm).

---

feii_hin  test feii in high density limit

title test feii in high density limit

This checks that, at high particle densities, in which the gas should be in collisional equilibrium, the level populations of the large model Fe+ ion go to the proper values, where the departure coefficients are all equal to unity.

c
func_distance.in
c class function
c=======================================
c
Normally the code predicts the intensity or luminosity of the emission lines. This test confirms that it can predict the flux received at the Earth instead. The model is the simplest and fastest that can be computed - a H-only constant temperature single zone. The total luminosity is set to 1e40 erg/s, and the ionization source is a laser at 2 ryd. With these set, the total luminosity in ionizing radiation, the total luminosity in the incident continuum (the emission line labeled "Inci 0") will be 1e40.

The code will predict the flux at the Earth if both the distance to the object is specified with the distance command, and this is requested with the print flux earth command. The distance was chosen so that the total flux at the Earth will be 1 erg/s. This is asserted at the end of the calculation.

c
commands controlling output =========
This test irradiates a set of grains with a true blackbody in strict thermodynamic equilibrium. We expect the grains (and everything else) to equilibrate at the blackbody temperature. The gas temperature is forced to the radiation temperature because the current molecule network (based on ISM approximations) does not go to LTE in the high-radiation density limit. The calculation asserts that all grain temperatures are very close to the radiation temperature.

c===================================
c
This test conditions of cosmic ray ionization. Solar abundances with no dust are assumed so this involves gas-phase chemistry alone. The Solomon process is disabled with the "no induced processes' command so H2 is mainly dissociated by cosmic rays. This forms a pair with h2_cr_grains, which does include grains.

This is a plane-parallel constant temperature cloud with only hydrogen and helium. The gas has a filling factor
of 0.1. Induced processes are turned off and a large H atom is used so that the hydrogen recombination
spectrum will be close to Case B. The calculation stops beyond the hydrogen ionization front, because of the stop efrac command (it needs this since this is a constant temperature calculation, so the usual lower-temperature stopping criterion does not apply). The asserts confirm that energy is conserved and that the hydrogen spectrum is correct.

c===============

This is one of the test cases from the Lexington Meeting suite of nebulae (Ferland et al. 1995). It is a grain-free hii_blister HII region, similar to inner regions of the Orion Nebula, except for the absence of grains. The set of lines entered with the print line sum command lists the most powerful coolants in this model. This is one of the tabulated quantities in the Lexington Meeting, and is a fundamental test of energy conservation in the code. The ratio of the sum of these lines to Hb is equivalent to the Stoy ratio, used for determining stellar temperatures.
The "dielec kludge 0" command is to turn off my estimates of the DR rates for those elements that had none. This was only to allow comparison with other calculations that did not make similar estimates. For an actual calculation I would not include this command, since the guesses are better than nothing.

the turbulence is to stop the balmer lines from becoming optically thick since few other codes include an actual H atom, but use case b instead. The Orion HII region does have an observed turbulence of about 8 km/s.

This calculation stops near the H+ - H0 ionization front, where the temperature falls below the default lowest temperature of 4000 K. This model would have continued into the PDR had a lower temperature been specified with the STOP LOWEST TEMP command.

This is an example of an H II region irradiated by a hard stellar continuum - one of the Mihalas NLTE stars. The hard continuum produces a negative He/H ionization correction factor, as discussed in Ballantyne, Ferland & Martin (2000). Refer to Hel ICF by Ballantyne, D.R., Ferland, G.J., & Martin, P.G., 2000, ApJ 536,

This is one of the "standard" models computed at the Paris and Lexington meetings on photoionization and shock calculations. A table in hazy compares the predictions of the current version of CLOUDY with predictions of a few of the other codes. It is necessary to iterate since some fine structure lines are optically thick. The set of lines entered with the print line sum command is used to obtain the total luminosity in detected lines, a measure of the Stoy temperature.

Checks:
- Hb close to case B, Q(H) 4861, intensities.
- Enter answers in Table Error! Reference source not found.

**igm_lalpha Ly alpha forest cloud**

title Ly alpha forest cloud
c
c commands controlling continuum =======
c ionized by cosmic background

c
This example demonstrates the behavior of the code in the low-density limit. The ionizing source is the cosmic background at a redshift of \( z = 2 \). The cloud is assumed to be optically thin to ionizing radiation, in keeping with the Gunn-Peterson test, so the double command is included, and an iteration is performed to converge the optical depth scale. Continuum fluorescent excitation of lines is important because the cloud is optically thin.

**igm_primal** cloud with primordial abundances exposed to background at \( Z=10 \)

c ==============

TODO - look at temperature struture - it has jitter at about the level of convergence, up and down. Temp jitter caused by eden jitter. This model is nearly isothermal, jitter measures noise in solver, and is great chance to pin this down.

This is a test of the behavior of the code in the extreme of photoionization by a relatively hard continuum, at low densities. The continuum is the galactic background, attenuated by a column density of 10^22 cm-2. Ionization by galactic background cosmic rays is included. Case b appears since this region is deep in the ISM, and the Lyman lines are quite thick. This example checks whether the ionization balance, thermal
balance, and electron density sum, are performed correctly in this limit.

Checks:
- Numerical stability of solution
- Thickness exact

c ===================================================
c
This model generates a large column constant density cloud similar to the hot phase of the interstellar medium. The continuum is punched to generate one of the figures in Part 2 of Hazy.

There is a strange feature between 1.7e-3A and 2.2e-3A that is the N emission (head starting at 1.7e-3A with O absorption at 2.2e-3A. This model is strongly enriched in heavies so many metal edges, esp O, are optically thick.

>>TODO 1 the guess of the thickness of the first zone is badly too small, because this model is collisionally ionized, and it used Stromgren length - better to use collisional balance and dr - as result of this the model takes far too many zones

---

ism_jura check rate H2 forms on grain surfaces

title check rate H2 forms on grain surfaces
c
This model started out life as the Tielens & Hollenbach 1985 pdr. The density was set to unity and the incident radiation field adjusted so that the two default grains have temperatures near 100K. The model asserts that the H2 formation rate on grain surfaces is close to the H2 grain physics Jura, M., 1975, ApJ, 197, 575 rate.

**ism_opacity  generate standard ISM opacity curve**

title generate standard ISM opacity curve

c c commands controlling continuum ========
table agn
ionization parameter -3

c c commands for density & abundances ========
grains no qheat
This example creates the file `ism_opacity.opc` which tabulates the total opacity of the gas as a function of energy. These plots are used in ISM studies to understand the transmission characteristics along a line of sight. The opacity depends on the dust to gas ratio, the gas phase abundances, and the level of ionization, all of which can be changed by altering parameters given above.

The model is of a 1 cm thick parcel of gas which is optically thin in the Lyman continuum and Lyman lines. As a result the hydrogen emission line spectrum is close to case C. The model iterates so that the predicted ionization and emission know about this.

Normalize to "CaBo" 4861 = 2.23

Print populations h-like

Print departure coefficients

Case A is a mathematical fiction; when the Lyman lines are optically thin continuum pumping must be important if the gas is ionized. Fluorescence is turned off with the no induced processes command. The density is set to a very high value (1015 cm\(^{-3}\)) so that the 2s-2p states are well l-mixed, in keeping with standard case A assumptions. As a result, collisional excitation would dominate the level populations, and hydrogen collisions must be turned off with the hydrogen collisions off command. The Ly* optical depth is set to a small value. The set dr command sets the zone thickness to 1 cm. The abundances are set to a very small
value so that the electron density is equal to the hydrogen density.

Checks:
- Departure coefficients for H, He levels
- Neutral fractions
- H* emissivity

  hden = 6
  init file "hheonly.ini"
  c
  c commands controlling geometry ========
  stop zone 1
  stop lyman continuum optical depth = -6
This tests the behavior of the code in the Compton limit. The incident continuum is a blackbody in strict thermodynamic equilibrium. Strict thermodynamic equilibrium is expected for all constituents of the gas. The input stream also lists the expected photon fluxes for the incident continuum; this tests the normalization of the continuum, and its distribution. Grains are included to confirm their behavior in the LTE limit. The set dr command sets the zone thickness to 1 cm.

Checks:
- Luminosity, photon flux, over various energy intervals, 4*J at 912143.
- Electron temperature exactly 2*10^5 K.
- Grain temperature forced to 2*10^5 K by radiative processes.

limit_conserve.in

class hii pdr

c=======================================

This checks that energy is limit_conserve. The code always checks that it did not radiate more energy than was absorbed. This calculation extends well past the photo-dissociation zone into fully molecular gas, so that all of the incident radiation is absorbed. Grains, CMB, & CRs are not present so that only the incident radiation field powers the gas.

Small changes can affect this model to surprising extents because of the presence of a major thermal front at the H0 - H+ transition region.

This is the limiting case pure hydrogen collisional ionization, There are no excitation or l-mixing collisions, so this tests whether collisional ionization - three body recombination works in detailed balance.

limit_lte_h_t50_coll  collisionally excited H in LTE limit

title collisionally excited H in LTE limit
c
This checks that the model H atom goes to LTE at high densities.

chg 06 aug 24, had not included collisional ionization, and so he-like departure coefficients were very large, around 202. comments said there were problems. turned on collisional ionization, no problems noted

chg 06 jul 22 with RP changes in high-n n-changing collisions the rates are now much smaller - needed to change density to be far higher and several quantities changed. at lower density (1e18 cm-3) the populations are very unphysical and runaway maser now occurs. this is only a homework problem and intended to only test n-changing collisions. with higher density this test is done.

c=======================================
c
This model is a test of the behavior of hydrogen and helium in the high density, collision dominated, limit. The temperature is preset, the hydrogen density is set to a very high value, and the ionization parameter is very low. The resulting model is collision dominated, so this case checks that the collision physics occurs in detailed balance. The predicted departure coefficients should all equal unity. The set dr command sets the zone thickness to 1 cm.

Checks:
- Hydrogen departure coefficients exactly unity.
- Helium departure coefficients near unity. (Density not high enough to bring helium departure coefficients exactly to unity.)
- H-, H2, H2+ H3+, and HeH+ departure coefficients exactly unity.

This is a test of the treatment of the diffuse fields, their transfer, and their effects on the ionization structure of a nebula. The comparison is made against the exact calculation published by Van Blerkom and Hummer (1967). The geometry is open, that is, similar to that assumed in most BLR calculations.

The diffuse ots command is entered in order to reproduce the Van Blerkom and Hummer results. The default assumption, outward only, does not agree as well. I changed the default from OTS to outward only to be in better agreement with predictions by Harrington and Rubin at the Lexington meeting. They have not checked whether their codes are in agreement with the Van Blerkom and Hummer paper.

Checks:
- Neutral fraction at illuminated face 5.8*10^-4.
- Location of ionization front at 7.8*10^16 cm.
- 34TOTL 486134 and 34CA B 486134 agree; both slightly lower than 34Q(H) 486134.
- Answers with OTS agree with 1967 results.

Test hydrogen ground state rec effic against vb+h exact results this is their case e) - "zero condition" their answer for H0/Htot at the illuminated edge is approx 5.8E-4, and a Stromgren radius of approximately 7.7E16 cm

c commands controlling continuum ========
c SED of central star
table read "star_kurucz_39600.dat"
c its flux of H-Ionizing photons
phi(h) 13.0
c
c this is to include velocity field in radiative transfer
turbulence 8 km/sec no pressure
c
c commands for density & abundances ========
This is a model similar in spirit to the blister geometry HII region model computed by Baldwin et al. (1991). Size-resolved Orion grains are included. The constant pressure command does a hydrostatic equilibrium structure. The predicted emission-line spectrum is affected by the reddening of the internal grains. The resulting t2 analysis produces artificial results as a result. This has an open geometry, the original BFM paper was a closed geometry. (This makes little difference). Background cosmic rays are also included although these should have little effect on warm ionized gas. The emission line spectrum is given in surface brightness units, as in the BFM paper.

`orion_hii_pdr` constant pressure H+ region/pdr

c class pdr
c ===============

This is the dense phase model presented by LePetit, Roueff, and Herbst in order to reproduce C2 and C3 column densities observed along the line of sight to zeta persei. This is our attempt at reproducing their calculation. This is the dense molecular phase, not the phase that produces H3+

If you do a thermal equilibrium calculation by removing the constant temperature command the kinetic temperature will be about three times larger than assumed in their paper.
pdr_HTT91  low-density PDR from HTT91

title low-density PDR from HTT91

commands controlling continuum =========
c first continuum is FIR hot grain continuum produced in
c unmodeled HII Region
c this is hot star continuum
black 30000
intensity 0.2 range 0.4412 to 1 Ryd
c this will remove all ionizing radiation
extinguish 24 0
cosmic rays, background

commands for density & abundances =========
hden 3
init file="ism.ini"
abundances he -1.01 c -3.52 n-8 o-3.30 ne-8 mg-5.89
continue si -6.10 s -5.10 cl-7 ar-8 fe -6.60
grains orion, abundance log 0.16 no qheat

commands controlling geometry =========
sphere
c stop when gas is fully neutral
stop efrc -10
c this is to stop at an intended place, since results would be
c very dependent on details if we stop on temperature
stop thickness 18.954
c stop when gas is cold
stop temperature 10 linear
c add this to mimic unmodelled neutral gas
double optical depths

c other commands for details =========
iterate 2
case b
turbulence 1.5 km/sec

commands controlling output =========
normalize to 157.6m "C 2"
c uv lines are strongly pumped by stellar continuum, break out contribution
print line pump
print line optical depths
print ages

punch overview last "pdr_HTT91.ovr"
punch dr "pdr_HTT91.dr"
punch molecules last "pdr_HTT91.mol"
punch results last "pdr_HTT91.rlt"
punch continuum units microns last "pdr_HTT91.con"
punch heating last "pdr_HTT91.het"
punch cooling last "pdr_HTT91.col"

This is the Hollenbach et al 1991 Low-density PDR The case b command appears because the Lyman lines
are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically
thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

there is very little CO in this model since it is not thick enough for the UV pumping lines to become optically thick

---

This sim has some interesting properties. The grain temp is so low that O freezes onto grains as H2O. This is so efficient that CO does not become well formed - the CO/C ratio only reaches 0.3. This is one of the tests in Rollig et al. 2007, A&A, 467, 187

c
This is the Tielens and Hollenbach (1985a, b) standard model of the Orion photodissociation region (PDR).
Specifically, this is my attempt at their Table 2 of paper 2, ApJ 291, p749. The case b command appears
because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman
lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral)
hydrogen atom.

**pdr_th85ism_cgto TH85 pdr with ISM grains and C > O**

title TH85 pdr with ISM grains and C > O
c c commands controlling continuum =========
c cosmic radiation background
background z=0
c cosmic ray background ionization and heating
cosmic rays, background

- The first continuum is FIR hot grain continuum produced in a unmodeled HII Region.
- Blackbody, $T = 75$ K
- Intensity 2.7 (total)
- 
- This is the attenuated hot stellar continuum.
- Blackbody, $T = 30000$ K
- Intensity 2.204 range 0.4412 to 1 Ryd
- This will remove all ionizing radiation.
- Extinguish 24 0

- Commands controlling geometry =========
- Simulate effects of gas we don't model.
- Double.
- Their turbulence.
- Turbulence 2.7 km/sec.
- Stopping criteria.
- This should be the one actually used.
- Stop AV 33.2 extended.
- Stop when gas is fully neutral.
- Stop efrac -10.
- Stop when gas is cold.
- Stop temperature 10 linear.
- Stop at thickness of 16.5 so that mole limit does not apply.
- Stop this calculation - that would make results very difficult.
- Stop thickness 19.

- Commands for density & abundances =========
- Hden 5.362
- This turns off some elements, and processes we don't need.
- So needs to come before the elements.
- Init file="ism.ini"
- This is the TH85 mix except C is raised by 0.2 dex, C and O lowered by his amount, so that C/O > 1.
- Abundances he -1.01 c -3.4 n-8 o-3.50 ne-8 mg-5.89
- Continue si -6.10 c1-7 ar-8 fe -6.60
- Use ism abundances but turn off quantum heating grains ism, abundance log 0.16 no qheat.
- Other commands for details =========
- Must iterate since many FIR MIR lines are optically thick.
- Iterate.
- This is a closed geometry, in Orion, veil covers 2pi sr.
- Sphere.
- Make Lyman lines very optically thick, which stops pumping by Balmer continuum.
- Case b
- This should run cleanly - turn down number of allow conv fails.
- Failures 3.

- Commands controlling output =========
- Normalize to "C 2" 157.6 m
- C UV lines are strongly pumped by stellar continuum, break out contribution.
- Print line pump.

This is one of the "standard" models computed at the Paris meeting on photoionization and shock calculations. A table in Hazy compares the predictions of the current version of CLOUDY with predictions of a few of the other codes.

The model is meant to represent a planetary nebula ionized by a very hot central object. As a result there is a great deal of He++ and the associated line and continuum emission is very important.

An age of 10000 years was set. This tests logic in the age command.

This is the Hollenbach et al 1991 Low-density PDR. The case b command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

there is very little CO in this model since it is not thick enough for the UV pumping lines to become optically thick.

This is the Tielens and Hollenbach (1985a, b) standard model of the Orion photodissociation region (PDR).
Specifically, this is my attempt at their Table 2 of paper 2, ApJ 291, p749. The case b command appears because the Lyman lines are vastly optically thick in this environment. If the command is removed the Lyman lines will be optically thin, which will result in fast fluorescent excitation of the (nearly totally neutral) hydrogen atom.

m17_P07.in  Pellegrini et al 2008 model for M17

title Pellegrini et al 2008 model for M17
c a brief description of its purpose
c
c commands controlling incident radiation field =========
c these give the shape and intensity
brems 8,500,000K
luminosity 33.5 range 7.35 to 176 Ryd
table star CoStar, 47,490K
Q(h) 49.63
table star CoStar, 45,335K
Q(h) 49.47
table star CoStar, 43,151K
Q(h) 49.30
table star CoStar, 41,209K
Q(h) 49.18
table star CoStar, 39,084K
Q(h) 49.08
table star CoStar, 36,982K
Q(h) 48.81
table star atlas, 34,914K
Q(h) 48.97

table star atlas,27,700K
absolute bolometric magnitude -8.5

table star atlas, 23,700K
absolute bolometric magnitude -7.5

table star atlas, 20,350K
absolute bolometric magnitude -6.6

table star atlas, 17,050
absolute bolometric magnitude -6.3

c
c commands for density & abundances =========
hden 2.065
abundances H II region no qheat no grains
grains PAH 10
grains orion 1

element Helium abundance -0.98
element Carbon abundance -4.14
element Nitrogen abundance -4.2
element Oxygen abundance -3.47
element Neon abundance -4.4
element Sulphur abundance -5.06
element Chlorine abundance -6.88
element Argon abundance -5.64
element Iron abundance -5.5
c these are to speed things up a bit
element limit off -6.9

c
c commands controlling geometry =========
radius 0.35355 linear parsecs
This is the magnetostatic model of the M17 H⁺ / H₀ / H₂ region presented in Pellegrini et al. 2007, ApJ, 658, 1119
