Analysis of larval otoliths from island and mainland populations using the Barium and Strontium. The analysis showed significant discrimination among island and mainland populations (MANOVA: $F = 15.762$, $p < 0.0001$) and the discriminant ability of the model was 65%. Solid boxes are ordination scores of recruits collected from Santa Cruz Island in 2002. Although an attempt was made to collect larvae on the mainland, the recruitment was so low that the sample was not sufficient for analysis.
